

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

MENSTRUATION AND ITS DERANGEMENTS.

By ALFRED MEADOWS, M.D., F.R.C.P. &c.,
Physician to, and Lecturer on Midwifery and Diseases of Women
and Children at, St. Mary's Hospital.

Abstract Report of Harveian Lectures for 1881.

(Continued from page 532, last vol.)

LECTURE III.

Dysmenorrhœa.—Pain, which is normally absent during ordinary menstruation, is a prominent symptom of dysmenorrhœa; [it is in certain cases so acute as to be comparable with the pangs of labour, and in some degree is invariably attendant on the derangement. The amount and regularity of accompanying discharges are both subject to considerable variations, and are of less diagnostic value than the pain that goes with them. This, moreover, is subject to changes of situation easily understood when it is remembered how intimately associated it must be with the distribution of nerve supply to the affected organs. Its origin is not in any distinct lesion of a particular part, but may be ascribed to different causes in different instances. Thus, it may arise in the ovaries; may be a consequence of uterine congestion; may be due to efforts made at expulsion of intra-uterine accumulations; or it may be connected with the act of ovulation itself. The causes are capable of arrangement under four heads, as follows:—

1. Constitutional (neuralgic).
2. Congestion of uterus, or ovaries, or both.
3. Membranous dysmenorrhœa.
4. Obstructive; (due to formation of uterine passages.)

This arrangement is a better one than that which makes only two divisions of the subject; but whatever arrangement of it may be made, it must always be kept well in mind that *pain* is the distinguishing symptom of dysmenorrhœa.

Neuralgic Dysmenorrhœa is that form of the disease to

which the term *constitutional* has been applied on account of the absence of any abnormality in the organs to explain the pain felt in them, pain being the only symptom experienced, post-mortem examination even revealing nothing to show the reasons for its existence. There is, however, some light thrown on the condition by the knowledge that the tuberculous and strumous diatheses predispose to it, as also does anæmia. Careful observation of the subjects of tubercle and struma has convinced Dr. Meadows of the necessity for recognising the two states as distinct from each other, certain well-marked differences serving to separate them. Thus, in the one case (tubercle) a nervous temperament predominates; whereas, in strumous persons the reverse is true, they being lymphatic in nature; and hence it is that the actual form assumed by the neuralgic pain is not the same in the two states. It never affects the uterus in strumous people; in tuberculous patients the uterus is always the seat of pain. In the former *cellular* inflammations are common; in the latter *serous* inflammations occur. And of eruptions, those that take place in strumous individuals are pustular, while in tuberculous women they are papular in character. All these points of difference together sufficiently separate the two classes of cases.

Ovarian pain is a feature of neuralgic dysmenorrhœa, and may occur in one or in both ovaries, though it is more common in the left than in the right, and is evidenced by tenderness on pressure, whether this be applied externally over the seat of the organ, or internally per vaginam. It also induces a feeling of nausea. In those instances where the uterus is affected as well, special pains referable to the cervix are felt; and the condition thus established has long been known under the name of the "irritable uterus." Pain of this description is severe, and persists throughout the whole of the menstrual period. It is not dependent on any obstruction, or on inflammation, but is truly neuralgic in all its characters. *Treatment* must, therefore, be devoted to subduing the general symptoms, while as a specific remedy one drug can be relied on to produce beneficial effects, viz., bromide of potassium, which, through the influence it exerts on the

vaso-motor nerves, is usually productive of ease. Conium also is of valuable assistance for the control of severe pain; it may be employed as a suppository in the way previously mentioned, or, when circumstances permit, introduced per vaginam. In unusually acute attacks, morphia injected subcutaneously may be called for, or hot baths containing laudanum. A general tonic treatment, with iron, &c., and hygienic surroundings, are also necessary.

Congestive or Inflammatory Dysmenorrhœa is characterised by the presence of pain in uterus, or ovary, or in both organs; it is persistent, and not as in the neuralgic form, confined to the period of menstrual discharge, although at these times it is much exaggerated in degree. The symptoms present indicate an inflammatory condition in the uterus or ovaries; the chief of them is a heavy, aching pain, attended with menorrhagia or with leucorrhœa, which last are wanting in neuralgic dysmenorrhœa. Newly married women, when of a neurotic temperament, are especially apt to contract this form of disease, and it is preceded and accompanied by acute vaginitis. Examined through the vagina, the ovary is found to be enlarged, tender, and swollen; the cervix is seen to be injected and deeply coloured, and to exude aropy tenacious mucus, sometimes tinged with blood. All these signs are wanting in the form first considered, so that diagnosis from it is rendered certain if they exist. The treatment consists in remedying the cause of the condition, and for this purpose depletion affords the readiest means, and leeches by far the most reliable agent for securing the necessary abstraction of blood. Rest, the vaginal douche, and a spare diet will help to bring about a speedy restoration. Iodides and bichloride of mercury have yielded good results in many of Dr. Meadows' own cases. For the reduction of pain the same plan may be adopted as already suggested, but inflammation must be first of all allayed in all these cases. Uterine displacements not unfrequently accompany this form of dysmenorrhœa, thus producing obstructions; whenever such flexions exist with inflammation, pessaries will be of service by affording relief by support; in no other way is benefit produced, and certainly the introduction of a pessary does nothing in itself to bring about cures in these cases.

Membranous Dysmenorrhœa is the most hopeless of any of the forms assumed by the disease; consequently it is one of the most interesting. It is now a generally received opinion that the whole mucous membrane of the uterus is shed at each menstrual period, but that under normal circumstances it comes away without any visible signs of such a complete exfoliation. Sometimes, however, a perfect membranous cast of the uterus is expelled, the utricular glands even being modelled on the extruded mass; and it is perhaps in the differences marking these two methods of shedding the intra-uterine membrane that the explanation of membranous dysmenorrhœa is to be sought. Various accounts of the process have been given in this connection, but none can be said to be a perfect answer to the question of its causation. The membrane has been very improperly regarded as an inflammatory product, or as following to excessive hyperæmia of the walls, &c., but Dr. Meadows concludes that it is present always in neurotic individuals, and in those of sedentary habits and loose structure, in whom activity of the ovaries is followed by extreme consequences by reason of the non-resistance offered by surrounding structures. The ovarian element indeed is a prominent factor in the production of membranous dysmenorrhœa, concerning which, however, we can hope to learn but little until such time as it may be possible to examine the uterus carefully, immediately after the casting of a membrane. Patients always complain of pain over the situation of the uterus, and this for days prior to the membrane being cast, while at the moment of actual expulsion agonising suffering is endured. Treatment of these cases rarely ends in anything but disappointment, and no instance of cure being effected is on record. As a means of relief, however, all causes of obstruction to

the flow of discharge should be forthwith removed, and the pain due to ovarian excitement met as before recommended. The general treatment should include attention to the liver, this organ always having an important relation in cases of the kind under discussion. Such remedies as bromide and iodide of potash, chloride of mercury, cod-liver oil, and wines may be resorted to with advantage; but counter-irritation, pure and simple, is productive only of injurious consequences in the subjects of membranous dysmenorrhœa.

Obstructive or Mechanical Dysmenorrhœa may be due to obstruction caused by—

1. Strictured cervix, the external or internal os, or both, being affected.
2. Flexion of the uterus.
3. Polypus or other tumour occluding the os uteri.

In all these four pain is produced; it always is present—one among other ills—in obstructive dysmenorrhœa. Various opinions are entertained regarding the consequences that arise from such obstruction, and in connection with them many points arise for consideration and discussion.

This form of difficult menstruation admits of easy and accurate diagnosis. Digital examination, aided by the sound, at once reveals the presence of a flexion when it exists; and there will be complaint of pain, of a bearing-down or forcing kind, which is experienced also during the inter-menstrual periods. Moreover, accordingly as the uterus is ante- or retro-flexed, so will the bladder or the rectum undergo concurrent disturbance. In every case of this kind the ovaries are matter for secondary consideration. The uterus is that organ which prominently claims the attention, and that it is flexion solely that is to be dealt with is revealed by the examination conducted with a view to finally determining the cause of disease. Polypus is excluded by the absence of menorrhagia; but in spite of the probabilities pointed at by the signs observed, it is only by employing the uterine sound, together with the fingers, that an absolutely unmistakable diagnosis can be obtained, the instrument alone proving the real nature of the evil by causing the swelling to disappear on its introduction into the uterus, and thereby precluding the possibility of a fibroid tumour.

CLINICAL LECTURES ON SYMPTOMS.

Delivered in the Wards of the Hospital.

By FREDERICK T. ROBERTS, M.D., B.S., F.R.C.P.,
Professor of Materia Medica and Therapeutics at University
College; Physician and Professor of Clinical Medicine at
University College Hospital, &c.

LECTURE II.—ON GENERAL SYMPTOMS AND CONDITIONS.

I PROPOSE to-day to discuss general symptoms and conditions, so far as to point out the phenomena belonging to this group for which you have to be prepared, and with most of which you ought to be quite familiar. The symptoms may be either subjective or objective; and they are often observed in various combinations. Some of them are very important, and will demand our special consideration on future occasions. General symptoms and conditions are frequently evident to the most superficial observation, and may attract immediate attention; of this fact you have several striking examples in these wards at the present time. In other cases we have to inquire about them, or to study them by objective or even physical examination. Without entering into details, it may be well to state that in your superficial examination of a patient, for the purpose of determining the presence of these phenomena, you should pay chief attention to the following particulars:—1. The attitude, posture, or gait of the patient; as well as his manner and actions. 2. The general physique and condition of the body, and its state of nutrition. 3. The face, as regards colour, vascularity, expression, any unusual state of the features, puffiness, &c. 4. The skin and subcutaneous

tissue generally, as to colour, temperature to the hand, state of dryness or moisture, softness or harshness, evident eruptions, dropey, &c. 5. The colour of the conjunctivæ, and of the mucous covering of the lips and mouth. 6. The hands and nails. 7. The hair. 8. The presence of prominent nervous symptoms, such as unconscionness of convulsions.

In order to enable you to comprehend the nature of the general symptoms and conditions which have to be recognised, and to remember them the more easily, I propose to group them under certain classes, but you must bear in mind that those belonging to different groups are often associated together in the same patient. They may be conveniently arranged as follows :—

- I. Mere SUBJECTIVE SENSATIONS.
- II. Symptoms connected with the GENERAL CONDITION of the patient.
- III. Symptoms due to certain evident ABNORMAL BLOOD-STATES.
- IV. Symptoms associated with PARTICULAR ORGANS.
- V. SPECIAL SYMPTOMS.

These divisions will include all phenomena which may be regarded as simple or elementary general symptoms, but I wish to call your attention to the fact that, taking a patient as a whole, we have various combinations of signs by which we recognise certain general conditions, or it may be even particular complaints. This constitutes a considerable and important part of what has been termed the "physiognomy of disease." I therefore propose to consider this subject under the following additional headings :—

- VI. Signs of certain PATHOLOGICAL CONDITIONS.
- VII. TEMPERAMENTS.
- VIII. DIATHESSES and CACHEXIE.
- IX. SPECIAL DISEASES.

Let us now briefly consider the several divisions which I have enumerated, but you will understand that at present I merely intend to give you a summary of what is included under each, without entering into details. These will have to be discussed on future occasions.

I. SUBJECTIVE SENSATIONS.—Patients often complain of certain more or less general subjective sensations, and their existence may be evident to the observer, while it is frequently his duty to investigate them. Of course you must be prepared for considerable variety in these sensations, but those of most consequence and frequency may be gathered under the following sub-divisions.

1. *Debility and Allied States.*—These conditions imply on the part of the patient a feeling of various degrees of deficiency and impairment of bodily vigour, and of physical or nervous power. They may be associated with, and in proportion to some obvious general objective state, which readily accounts for them; but this is by no means always the case. Now it is of much consequence that you should have a tolerably clear conception of what you mean when you use certain terms indicative of symptoms belonging to this group, for there is really much confusion in their employment, which leads not uncommonly to serious mistakes. In this matter you must be particularly cautious in accepting what patients tell you about themselves. You must, at the outset, bear in mind that when they complain to you that they are suffering from "general debility," it may be nothing more than malingering, laziness, or selfishness, the individuals being indisposed for any effort; wishing other people to do everything for them, and attend to their every want; and having a desire for all the good things of this world, in order to "keep up the system." On the other hand, be careful not to mistake between supposed debility and actual paralysis from nervous disease. The real symptoms belonging to this class present gradations, which may approximately, for convenience sake, be arranged thus :—

- (a) Simple general debility or weakness, characterised by a feeling of languor or lassitude, want of energy and vigour, indisposition for effort, and a sense of general tiredness or fatigue easily produced by any exertion, often with aching in the legs and back. These phenomena exhibit variations in degree in different cases.
- (b) A state of physical depression and exhaustion, more or less marked, but sufficient to attract attention, and to be evident to the observer. This may be associated with corresponding mental depression.
- (c) Actual bodily prostration, or a condition of so-called *adynamia* or *asthenia*, the patient being, in extreme cases, absolutely helpless and powerless, so that he cannot stand,

or it may be even move in his bed, or raise his head from the pillow.

These divisions will perhaps enable you to understand the degrees of debility which you may meet with in practice, and will guard you against calling conditions by wrong names. For instance, patients are not uncommonly said to be in a state of exhaustion or prostration, when these terms do not in the least apply to the case.

2. *General Pains.*—Apart from the sensations alluded to in the preceding remarks, general pains constitute a symptom not uncommonly requiring attention. They are usually experienced mainly in the legs and back, but may affect the whole body. They are either fugitive or persistent. Of course these sensations may, like those of weakness, mean nothing, but they are often important, as indicating the onset of some acute febrile disease; the effects of a general "cold;" or undue exertion, and consequent muscular waste and fatigue, or muscular rheumatism. It must also be remembered that so-called "general pains," felt in various parts of the body, may be premonitory of serious diseases of the nerve centres.

3. *Peculiar Sensations.*—Under this head may be mentioned sensations of cold or "chills," often attended with shivering, and culminating in more or less marked and evident rigors. With this may be associated a feeling as if cold water were trickling down the back. Some persons feel habitually cold and wanting in vitality, especially when suffering from certain diseases. As temporary phenomena, the sensations mentioned are often premonitory of fevers or febrile paroxysms, or of acute inflammatory diseases, as is well exemplified in ague, in the night pyrexia of many cases of phthisis, and in acute pneumonia. Other sensations belonging to this category are "heats and flushings," of which women frequently complain, coming on at intervals, and the flushing may be objectively visible in the face and neck. Sometimes patients have sensations which they cannot explain. They feel "out of sorts," but cannot definitely say in what way, and even such sensations may be of importance to note.

4. *Nervous Sensations.*—As I have already indicated, you must be prepared for all sorts of queer and inexplicable sensations, referred by hysterical and other morbidly-minded individuals to the whole body, or to various parts and regions. It is impossible to attempt any description of these, for they are as diverse as they are incomprehensible. You will seldom have much difficulty in recognising their nature if you exercise ordinary care.

II. SYMPTOMS CONNECTED WITH THE GENERAL CONDITION.—I include under this head certain objective phenomena, affecting more or less the system as a whole, and which you may either notice at once, or ascertain by investigation. It is always well to take a comprehensive survey of any patient who comes before you, so as to determine the general build and conformation, and the degree of apparent robustness and vigour. The conditions, however, to which your attention needs to be particularly directed are chiefly these :—

- 1. Various grades of general wasting, culminating in the most extreme emaciation.
- 2. Want of tone in the muscles, with flabbiness of the tissues generally, which may or may not be associated with perceptible wasting.
- 3. Obesity, or excessive accumulation of fat throughout the system. This is often combined with flabbiness of the tissues, and defective tone.
- 4. Objective coldness and want of vitality, often evident in the appearance of the individual, or perceptible to the touch.
- 5. Certain conditions of the skin generally, namely, dryness and harshness; marked scurfiness; want of elasticity; more or less profuse sweating; and peculiar discolourations.
- 6. Signs of agedness or senility, or of premature decay and degeneration; or, on the other hand, of imperfect and delayed development. It is frequently important to compare a patient's real with his apparent age.
- 7. An appearance of "looking ill." It sometimes happens that a patient's general aspect at once convinces you that there is some serious illness, acute or chronic, and yet you may not be able to define exactly what you observe, or to put it into words. I would recommend you to be alive to such impressions, and not to ignore them when they come upon you. I may also mention that patients sometimes wear a care-worn aspect, and present an expression of mental depression or worry and anxiety, which may be a

sign of some existing or threatened illness of importance, or may draw attention to the cause of an ailment. Such appearances are worthy of note in any case in which they are present, and you should be on the watch for them.

(To be continued.)

LIGATURE OF RIGHT COMMON CAROTID FOR ANEURISM BY ANASTOMOSIS IN RIGHT PARIETAL AND TEMPORAL REGIONS.

By M. O'MALLEY KNOTT,
Surgeon to the Mayo Co. Infirmary

BRIDGET CONNOLLY, *æt.* 18, a native of the neighbourhood of Ballyhannis, about thirty miles from Castlebar, was admitted to the Mayo co. Infirmary on September the 10th, 1881, suffering from the effects of severe hæmorrhage, which proceeded from a tumour extending from the external corner of right eye to the parietal protuberance of right side of head. She was blanched, nervous, and desponding; pulse hæmorrhagic; visible throbbing of both carotids, and great excitement of the circulation generally. The temporal portion of the tumour was red in colour, soft, elastic, and pulsating; the parietal portion was concealed by matted hair and clotted blood, and also pulsating.

The history of her case is as follows:—

At birth she had a small tumour in the parietal region, which gradually increased in size, until at last it caused her some uneasiness, and two years ago was advised to go to Dublin for treatment, and was admitted into hospital there, where she remained for a considerable period, and no doubt would have undergone the treatment her case required, had not the surgeon whose care she was under got ill; and the hospital was undergoing repairs. Under those circumstances she was discharged, with directions to return again after a time, which she did not do. From that period until she came under my care the tumour was increasing in size and extending towards the temple, and was nearly as large as a small hen egg. A short time before I saw her some slight irritation took place on the most prominent part of the parietal portion, which she scratched, and a small scab resulting, came off in the act of combing her hair. This caused most profuse hæmorrhage, from which she fainted. This first loss of blood took place five days before, and on the night previous to my seeing her, it burst again, and bled profusely, but was ultimately controlled by her mother using pressure, and her own hair helping to form a clot, which stopped it for the time. When she arrived at the infirmary it was evening, and I put off making any minute examination until the following morning. It burst again in the night, but was quickly controlled by perchloride of iron and pressure applied by the resident apothecary. Next morning I carefully removed the clotted hair, and exposed the tumour to view; it was slightly ulcerated at the point of bleeding, extending between the points already mentioned about three inches wide, at its parietal portion decreasing to a neck about an inch, before dilating again to form the temporal tumour; the surface was inflamed and angry-looking; oval in shape, with ill-defined margin, and seemed rapidly spreading over the scalp. The more I looked at it the less I liked its appearance; it did not look at all inviting to attack with either needle or ligature, also its flat shape and ill-defined margin had rather a discouraging appearance for operative interference at that time, so to try and prevent the fierce hæmorrhage which might take place at any moment, and as the girl was in too exhausted a condition to bear any further loss of blood, I made up my mind to tie the right common carotid, which I did next morning, on September 12th, being kindly and ably assisted by Doctors Jordan, Dwyer, and Lyden. The girl was put under ether with Ormsby's inhaler, which acted expeditiously and satisfactorily in every respect. The various steps of the operation were easily accomplished, no trouble from the vein which was seen rather posterior to the artery, and the loss of blood during the

time was almost *nil*. The ligature used was thin whipcord. After the effects of the ether passed off, to have every three hours *Tr. aconite gr. v.*, *Tr. digitalis gr. x.*, which she got during the night. On the 13th her pulse was much quieter, and skin cooler than on the previous evening, to continue mixture *ter in die*; as the bowels were confined to have *haust. sulph. mag. c. acid sulph. dil.*

14th.—Bowels opened; pulse quiet; no fever. Omit *mist. aconite et digitalis*. No further treatment but dressing the wound with diluted *lotio detergens carb.* The ligature not interfered with, and came away of its own accord on October 1st. In the meantime, the tumour got smaller, and lost much of its congested appearance, and I was hoping it would require no further interference; but a few days ago, after the ligature came away, it increased in size again, and had all the appearance it presented at first, and on the night of the 8th it again burst in the old spot. I found that by applying pressure to the neck of the temporal portion it could be almost emptied, so I introduced a strong, straight needle at that point, and bound it tightly with a figure-of-eight ligature; and although it almost obliterated the temporal part, the parietal portion became much increased in size, and looked like bursting at any moment, it also became more defined in form and easier to ligature, which was done after a brief consultation with Drs. Dwyer and Lyden. The method of doing so was according to that recommended by Erichsen, in his surgery, vol. 1., page 717, and figure 257, of the edition, 1872. The plan acted admirably, no blood was lost during the operation, and, after an anodyne was given, the girl suffered much less pain than I expected—in fact, had none after the night.

On the 15th I again introduced a needle through the base of the tumour, armed with a strong, double ligature of whipcord. After drawing out the loop I cut it, and tied both ends tightly, so as to make sure of strangulating the mass.

On the 16th she was attacked with erysipelas of the right side of the head and face; ordered a diaphoretic, with small doses of digitalis every three hours; diet nourishing, and non-stimulating.

At this period of the case I was obliged to leave home for a fortnight, and left her in the care of Dr. Lyden. He told me the erysipelas rapidly disappeared; and when I returned on November 1st I found her general health very good, a large granulating surface, but with a portion of the tumour, still remaining, though much smaller and shrunken in appearance than when I left home. It had a tendency to sprout again. I then re-applied the double ligature, as on October 15th; and on the 2nd of November it also came away, leaving a clear, granulating surface, which has healed now to about the size of a shilling, and is rapidly getting less. All enlargement of right temple is completely gone, the skin has resumed its natural colour, and the girl is to be discharged to-morrow.

My reason for giving aconite and digitalis after ligaturing the carotid is, that in the year 1863 I assisted my father in tying the carotid of a policeman for a wound in the neck. I was then struck with the great disturbance of the circulation and fever which supervened. I do not remember what treatment, if any, was adopted. The man died on the 43rd day after the operation. About twelve years ago I tied the carotid of a child, seven years of age, for a wound of the right tonsil, caused by the sharp point of a slate pencil. In this case, also, the circulatory disturbance and fever were very great, and the child died on the 16th day. To obviate this excitement, I prescribed the above, and whether caused by the medicine or not, the result was gratifying to all parties.

THERE were 50 deaths from diphtheria in New York in the week ending the 26th ult., being equal to the death-rate from the same cause throughout the United Kingdom. The disease is also epidemic in Berlin.

THE TREATMENT OF SIMPLE CHRONIC CORYZA.

By Dr. LOWENBERG.

Translated from the *Union Medicale*,

By ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S.I.

SIMPLE chronic coryza is a common disease, but it very often refuses to submit to any form of treatment. It is very troublesome to invalids of all ages, being prevalent among infants, as has been shown by the researches of Rayer and Billard.

Simple chronic coryza is accompanied by tumefaction of the pituitary membrane, alteration in the quantity and quality of the nasal secretions, and other troubles.

The sense of smell becomes weaker, sometimes being almost entirely destroyed, and the taste loses its acuteness. The obstruction of the nasal fossa prevents the pronunciation of certain letters, and produces a nasal tone, in fact, from the time that the hypertrophy of the pituitary membrane attains a certain point, the inspiration can no longer be effected through the nose, and the patient must resort to buccal respiration, which causes the rather nasal sound arising from the half-open position of the mouth, and produces an injurious action on the pharynx by the air which strikes it directly.

I will not now enlarge on these phenomena, having explained them in detail in a former work. The principal object of this paper is to increase the *therapeutic* treatment of simple chronic coryza. But before touching this subject I think it desirable to speak of a complication which frequently comes under our notice. It is a *special malformation of the septum*, which I have often observed and which helps to contract the nasal fosse, and is very much exaggerated among those suffering from coryza. The disease shows itself in the form of conical projections situated on the septum, and spreading towards the exterior wall of the nose. These spur-like formations are generally to be found in the vicinity of the Eustachian, and often affect both sides of the septum at one time. As it is especially on the mucous membrane of the lower ear, that hypertrophy in chronic coryza appears, the end of these formations often touches the lining membrane of the interior ear, and obstructs the entrance of *nasa fossa*. This makes an important difference, according to my observations, in the treatment of the malady with which I have to do at present and also in catheterism of the Eustachian, but this last peculiarity will be treated on another occasion.

Therapeutic Treatment.—As the development of this malady is slow, and especially at the beginning there are momentary means of relief, some of those suffering from it accustom themselves to it, others less resigned fight against it and use many different remedies; mineral waters are often employed—in baths, by drinking, and by local applications. I do not deny that by these means a certain number of maladies may be relieved. A general treatment conducted with discretion, can certainly act on diathetic dispositions which are, in this instance, most plentiful. Local applications influence favourably the anomalies of secretion, but only when they are used with prudence. Experience has taught me that though the nasal fossa can support in a most surprising way certain trying treatments applied with a perfect knowledge of their use, yet they are extremely sensible to some which are to all appearance very innocent, and quite common in their use. Thus, that most powerful agent, the galvanic-cautery handled by an operator accustomed to use it, exercises a most beneficial influence on the Schneiderian membrane, causing only a slight reaction, while, the nasopharyngeal douche of Veber formerly an excellent remedy, can provoke extraordinary kinds of irritation when it is badly employed, for example when instead of using saline solutions capable of moderating the osmotic changes they substitute liquids which favour them, such as pure water. I ought to say after a long experience, that the usual therapeutic treatment, no matter how prudently and judiciously employed, is powerless alone to destroy the origin of the chronic coryza, the hypertrophy of the pituitary membrane, and the principal symptoms of this disease, all of which arise from modification of the mucus. The swelling resists the most skilful treatment, and even

grows under the influence of certain applications, it only submits to the use of the galvanic cautery, and the object of the present work is to make known the advantages of this instrument. The galvanic cautery recommended for affections of the nasal fossa by Messrs. Vitolini, Michel, Zauffel, Redinger, &c., causes the swelling to decrease rapidly, re-establishes the nasal respiration, and often restores the sense of smell. Its action produces definite results, that is, the enlargement of the mucous membrane disappearing, never returns; and this no other method of cauterism would be able to do as safely and easily as the present one. The galvanic cautery determines in the pituitary membrane hypertrophy. The portions removed remain open as if they had been made by a gouge, and the spaces thus obtained re-establish the normal size of the nasal cavities. The application of this agent, which is such a powerful one, causes very little pain, and the reaction is very slight. The incandescent plate can be made to penetrate into the mucous membrane which covers the internal ears without any complaints from the patient, and without any violent inflammation following this operation which appears so hazardous. This agrees with what we know about the slight reaction following galvano-caustic operations in general, and the rapid change they bring on. I have succeeded in causing the definitive disappearance of the nasal obstructions in the three or four sittings lasting each some seconds, by confining myself to limiting the engorgement of the internal and middle ear. I have had lately the care of a little girl, aged 4 years, who suffered for some time from coryza. The internal ears were so swollen that all trace of the nasal fossa had disappeared; six applications sufficed to disengage the interior and middle and re-establish respiration through the nose. Although troublesome, these cauterizations caused so little pain that I was able to continue them without using any coercive means or rendering the little patient insensible. With very young children the coryza produces grave phenomena, for while sucking they cannot respire at all. I never hesitate in a case of this nature to employ the galvanic cautery, especially of that model which I will describe further on, to diminish instantly the swelling of the mucus and re-establish the nasal respiration, which is the only one which infants know how to make use of.

Special.

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

NEW TROCAR FOR OVARIOTOMY.—At the Société de Chirurgie, M. Dupony exhibited a new trocar for ovariotomy, and which fixed the walls of the cyst during the puncture. M. Lucas, although giving every credit to his colleague for his ingenious instrument, did not consider the fixation of the walls of the cyst as absolutely necessary, and that, instead of multiplying ovariotomy instruments, their simplification should be sought. English surgeons reproach French ovariotomyists with having a too complicated apparatus, and, with antiseptic precautions, it mattered little whether a teaspoonful or two of the liquid found its way into the peritoneum.

IOODOFORM DRESSING.—M. Sée employed for some time back iodoform in dressing every kind of wounds. To-day the same treatment was generally adopted in Germany, and with the best results. M. Sée uses it in every kind of ulcer, surgical wounds that will not heal by first intention, and jagged wounds in which pus stagnates easily. I fill in these cases, said M. Sée, the cavity with powdered iodoform, and immediately the pus ceases to be secreted. It is a very simple and easy dressing, and has none of the complication of the Lister dressing, and succeeds just as well. It has two inconveniences, however, it is dear and smells strongly. M. Després has twice employed iodoform in the dressing of wounds, and each time the patient refused the treatment on account of the bad smell it produced. He would like to know from M. Sée how long his wounds took to heal. As for him (M. Després) he would guarantee to cure any simple ulcer by rest and cataplasms. M. Terrillon said that in a journey he made to Vienna he had seen in the service of Billroth iodoform dressing employed on a large scale, and yet he did not perceive any odour in the wards. The following is how it is employed by that celebrated surgeon:—A piece of ordinary gauze is taken and freed from stiffness by steeping it in warm water, when dry it is triturated in powdered iodoform and

then it is ready for application. To disinfect this agent a drop or two of essence of bergamot or peppermint. In total ablation of the uterus through the vagina, M. Billroth said that he had obtained excellent results from plugging the vagina with this iodofomed gauze, and renewing it every eight days. M. Verneuil considered iodoform to be an excellent topic for ulcers of a bad nature, but he did not employ it in surgical wounds. As for soft chancres, no dressing can be compared to it for efficacy and rapidity of action. These chancres are healed in three or four days. In scrofulous ulcerations the action of iodoform is also marvellous. Its bad odour can be corrected by mixing it with an equal part of powdered camphor. In a word it is a very precious agent. M. Trelat also believed that iodoform renders great services in local applications. M. Després, on the contrary, insisted that any other kind of dressing was equal to iodoform, which he considered a vulgar counterfeit of iodine. His method of treatment, although belonging to the old school, succeeded just as well, and cost less. M. Sée terminated the discussion by thanking the members for their valuable information, and added that the iodoform succeeded just as well in deep-seated lesions, as in those on the surface; for he had seen white fungous swelling of the knee-joint cured by injections of this agent dissolved in ether.

HERNIA OF THE OVARY IN THE INGUINAL REGION.—A little girl, *æt.* 6 months, was brought to the service of Prof. Boeckel, of Strasbourg, presenting in the left inguinal region a tumour of the size of a pigeon's egg. The skin which covered it was red and inflamed; the tumour itself was hard, very painful, and irreducible. It was situated at the external orifice of the inguinal canal. It was perceived for the first time three months ago, and was then about the size of a nut, and being reduced by a medical man, it did not make its reappearance until a fortnight before admission into the hospital. The child cried night and day, vomited frequently, and got thin. The bowels continued to act tolerably well. On examination hernia of the ovary was diagnosed, and chloroform being administered, reduction having become impossible, an incision was made over the tumour dividing the skin, and subcutaneous cellular tissue, when the ovary was brought to view, enveloped in its sac. Incision of this sac gave exit to a few drops of colourless liquid. A silk ligature was thrown around the pedicle, which was formed of the Fallopian tube. The wound was dressed antiseptically, and at the end of nine days the ligature fell, and the cure was complete at the end of thirty days. The section of that ovary included half an inch of the Fallopian tube.

The mortality last week in the large towns from diseases of the zymotic class per 1,000 of the population were:—From scarlet fever, 10·4 in Hull, and 3·1 in Nottingham; from measles, 3·5 in Plymouth, and 3·4 in Leeds; from whooping-cough, 2·1 in Wolverhampton, and 1·9 in Brighton; and from "fever" (principally enteric), 2·3 in Oldham, and 0·8 in Leeds. In Hull 31 more fatal cases of scarlet fever were recorded, raising the number registered within this borough since the beginning of July to 618. The 53 deaths from diphtheria included 19 in London, 16 in Portsmouth, 7 in Glasgow, 3 in Birmingham, and 2 in Sheffield; the 16 in Portsmouth considerably exceeded any previous weekly number since the commencement of the present epidemic more than twelve months since, and were equal to an annual rate of 6·5 per 1,000. Small-pox caused 28 more deaths in London and its suburban districts, one in Nottingham, one in Liverpool, one in Oldham, and one in Newcastle-upon-Tyne; no fatal case was returned in any of the other large towns.

The rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their population were—Newcastle-on-Tyne 17, Sunderland 18, Norwich 19, Brighton 20, Portsmouth 21, Sheffield 21, Wolverhampton 21, London 22, Bristol 22, Nottingham 23, Edinburgh 23, Birmingham 23, Bradford 24, Glasgow 25, Oldham 25, Manchester 28, Plymouth 28, Salford 28, Leicester 29, Liverpool 30, Hull 30, Leeds 30.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 4, 1882.

THE COLLEGE OF PHYSICIANS ON CONSUL- TATIONS WITH HOMŒOPATHS.

ON Tuesday, December 27th last, an extraordinary meeting of the Royal College of Physicians of London was held, at which the following resolution was proposed by Dr. Wilks, and carried without a dissentient voice.

"That, while the College thinks it desirable not to fetter the action of the fellows, members, and licentiates, with reference to any opinions they may adopt, it nevertheless expresses its opinion, that the assumption or acceptance, by members of the profession, of designations implying the adoption of special modes of treatment, is opposed to those principles of the freedom and dignity of the profession which should govern the relations of its members to each other and to the public; the College, therefore, expects that all its fellows, members, and licentiates will uphold these principles by discountenancing those who trade upon such designations."

The discussion which preceded the passing of this resolution was interesting in many respects, but perhaps Sir William Gull's brilliant suggestion to debate the matter with closed doors was the most remarkable incident that marked the day's proceedings. What possible benefit the profession of medicine would derive from a secret resolution, the terms of which could necessarily be known to but a few of those most nearly concerned with it, requires more penetration to discover than we are able to lay claim to. Sir Wm. Gull's motives cannot, of course, be misconstrued; nevertheless, it is

a curious fact that he should deem it advisable to relieve "the most respected Fellows" of the difficulties they encounter by disagreeing with the outspoken protest against consulting with unscientific practitioners by means of an official declaration which can, at pleasure, be invoked to approve or condemn, as the case may be. We may well express unfeigned satisfaction with the reception accorded to the proposition of Sir Wm. Gull, which, if accepted by the College, would have gone far to alienate from it the sympathy and respect of the great body of medical men, not only in this country, but abroad also. Dr. Andrew Clark, though he refrained from placing any proposal before the meeting, succeeded in proving the unalterable consequences that must follow any *bonâ fide* consultation between legitimate practitioners and the professors of a school of medicine by describing such consultation as false and immoral; and although it was hardly to be expected that the College of Physicians would actually endorse assertions of such a sweeping description, still it has practically admitted the justice of their application to the matter in hand. Dr. Wilks, indeed, has shown himself conscious of all this, while, at the same time, he has carefully avoided the appearance of extreme measures, which, very possibly, a majority of the profession would unhesitatingly accept, if sanctioned, by a recognised authority. At the present time, it must be allowed, the course that has been pursued is the one best calculated to serve a good purpose; the resolution is temperate without temporising; it is decisive without destroying; and it is *definite* so far as it extends. It makes no attempt to dictate either the lines or the limits of scientific medicine; it duly recognises the sanctity of individual opinions; it seeks only to impose legitimate and proper restrictions of an ethical kind, such as it is the function of the College to decide; and it is possible to hope for good to follow from its actions.

DR. BATTY TUKE ON BRAIN HEALTH.

It is a healthy sign of the times that health lectures are attractive to the masses, and that the words of the late Lord Beaconsfield *sanitas sanitatum omnia sanitas* are no longer regarded as an epigram or hyperbole, but as the statement of a simple truth. There is an ever-growing appreciation of the fact that health underlies individual happiness and social prosperity, and that some knowledge of the human economy, and its laws of action, is a useful acquisition. There is an increasingly zealous pursuit of this knowledge wherever it may be obtained, as was well shown in Edinburgh on the 10th ult., when the Free Assembly Hall, one of the largest buildings in that city, was densely crowded by a highly cultivated audience, anxious to hear Dr. Batty Tuke lecture on the "Brain and its Functions." So eager were the good people of Edinburgh for authoritative information on this subject, that the hall would not contain all those who sought admission to it, even although its passages were closely packed with gentlemen who had to stand during the delivery of the lecture. And Dr. Batty Tuke's lecture was well worth even the inconvenience of having to stand an hour in order to hear it, for it set forth with much freshness of style, and with singular lucidity, the results of the most recent

researches into the structure and functions of the complex organ of the mind. Beginning by stating that nervous matter pervades all the bodily structures, with the exception of bones and gristle, he explained how all nerves gradually converge through the spinal cord to the brain, how fibrils, fibres and nerves are formed, and how the insulation of nerve fibres is provided for. In the brain and spinal cord he pointed out the external envelope of the fibres is not present, the cells and fibres being there imbedded in a connective tissue peculiar to themselves, called neuroglia or nerve-glue, which was, Dr. Tuke thought, a bad name, inasmuch as it suggested the idea of an adhesive substance, whereas the structure was a delicate reticulated net-work of fibres pervading the whole organ. Speaking of the brain proper, the lecturer observed that it did not attain its maximum weight till the twentieth year, while as regards the allegation that its average weight has diminished in this country during the present century, he could only express his entire disbelief in it. In dealing with the minute structure of the cerebrum, he was able to demonstrate, by means of the oxy-hydrogen light, and two beautiful sections of the brain, which Dr. Hamilton, Pathologist to the Royal Infirmary, had succeeded in mounting on slides, the relations and constitution of the grey and white matter.

Dr. Tuke did not, of course, seek to introduce into a lecture, delivered to a popular audience, any new views, or discoveries, or controversial matter, his object being to convey in language, free from technicality, a clear and just conception of the supreme crown of the nervous system, as it has been made known to us by modern scientific methods. It is unnecessary, therefore, to reproduce what he said in a medical journal, although much of his prelection might even merit a reproduction of that kind on account of the clear, forcible, and happy style in which it is put, a style which occasionally even imparts something of novelty to an old familiar fact. But besides a succinct and graphic description of the anatomy and physiology of the brain Dr. Tuke's lecture contained many incidental observations that are worthy of professional, as well as general, attention. Thus when explaining localisation of function in the brain, and bestowing praise on Ferrier's researches, he indicated the direction which further inquiries in this department should take, and deplored the restrictions which are now placed on physiologists by legal enactments, which must inevitably retard the progress of the healing art. In connection with nervous exhaustion, one of the prevalent maladies of the day, he showed by what kinds and conditions of mental work it is induced or warded off, and in connection with the power of attention he offered some useful hints as to how to secure efficient and safe service from railway officials, on whose power of sustained attention the lives of all us so frequently depend. The lecture was altogether a most instructive and practical one, and we are not surprised that it was imbedded in a neuroglia of applause.

THE DISHONESTY OF IRISH UNION MEDICINE SUPPLIES.

A LITTLE over three months ago we announced that the Local Government Board of Ireland had issued a new form for the supply of medical requisites to dispensaries. We

shall now give some experience of the method by which the annual supplies of medicine have been tendered for. We have before us two tenders, one by a local druggist, whose prices we have good reason to believe are based on those of a London firm: the other by a wholesale firm which supplies many unions in Ireland. These tenders we shall designate R. and W. respectively. They certainly present a curious study alike to the financier and the moralist. There are 299 articles tendered for at prices varying from *one-fifth* of the list price of a good article to *double* that price. The two tenders also differ in an extraordinary way. R.'s price being sometimes twice as much as W.'s, and again W.'s price being sometimes five times above R.'s, with every variation between these extremes. And yet, strange to say, differences so compensate each other, that on the whole 297 articles there is only a difference of four per cent. between the two tenders. Amid this apparent confusion it is possible to discover the operation of certain laws of a very peculiar kind. Thus, there are 13 kinds of official pills to be tendered for, and a price is to be quoted for each under two forms, as "mass," or divided into pills, and "coated." Of course, every medical officer will choose to have his pills ready made. R. quotes the pill masses $63\frac{1}{2}$ per cent. *below*, and coated pills 23 per cent. *above* list price. W. quotes pill masses $42\frac{1}{4}$ per cent. *below* and coated 6 per cent. *above* list price. Again, the quotations for tinctures present a curious study. There are 45 official tinctures in the list. R. quotes 30 of these at the all round price of 2s. 6d. a pint, wholly irrespective of the ingredients, and of several of them being required to be made with rectified spirit. W. has more variety in his prices, but the result on the whole is that W. is 43 per cent. and R. 30 per cent. *below* the list prices. We have already noted that the coated pills are quoted above list prices. It is singular that those articles which are tendered for by the ounce or drachm are much above the average price of those tendered for by the pound or pint. They are frequently up to or even above the list price. However much the two tenders differ, the operation of these laws we have indicated is uniform in both of them.

As examples of individual prices we may instance the following:—Co. colocynth pill mass, which is 20s. per lb. if made with virgin scammony, and 10s. if made with resin of scammony, is quoted at 2s. per lb. by both R. and W. Tinct. hyoscyam, the list price of which is 5s. per pint, is quoted as 1s. 4d. by W. and at 2s. by R. Tinct. rhei co., of which list price is 3s. 6d., is quoted at 1s. 4d. by W. and 2s. 6d. by R. On the other hand, Ext. filicis liquid, the list price of which is 12s. per lb., is quoted at 1s. 6d. an ounce by W. and 1s. 4d. by R., that is, 24s. and 21s. 4d. per lb. Chart epispastici, the list price of which is 4s. 6d. per dozen, is quoted by W. at 5s. and by R. at 1s. per dozen.

We need not proceed further in our analyses of these tenders or in our comparison of the fair trade prices of drugs with those charged by Irish union drug contractors. Whatever conclusion the pharmacist may come to as to the honesty of the prices charged for individual items of the supply tendered for, there cannot remain on the mind of anyone a doubt that one or other of these druggists is guilty of an audacious swindle, and probably of

the additional crime of selling fraudulent drugs, and cheating the ratepayers by supplying to the poor medicines other than those contracted for. By no conceivable means could all the prices which we have quoted be even approximately honest, but so callous to the disgrace of commercial fraud are some traders, and so free are Irish drug contractors in general of any apprehension that their lucrative trickery will be interfered with, that they do not hesitate to avow their dishonesty on the face of their signed tenders.

That the Irish Local Government Board—whose special function it is to check the expenditure of the poor-rates, and to see that the sick poor receive proper medical treatment—should patronise a system which they know to be corrupt and nefarious, is a public dishonour to them. The Irish Poor-law Commissioners have known for years past that the sick poor are commonly physicked with rotten, adulterated, and therapeutically useless medicines. They have known also that for the rubbish supplied for this purpose monstrously extortionate prices are obtained by the contractors. They have known also that fair trade competition in quality and price of union medicines has become impossible, because, under the patronage of the Local Government Board, a system of tendering is permitted to which no respectable drug merchant would condescend. They know that these abuses have arisen from leaving the selection of medicines to bucolic Poor-law guardians, who have neither care nor education for the task.

The Irish Local Government Board of the past, we say, must have known all this, for most dispensary doctors, and every drug trader in Ireland know it, and any one could prove the truth of our assertion by an examination of the drug tenders which we have before us.

What excuse, then, can there be for the official toleration of this system by the Board, and for their omission to do their duty towards the public and the sick poor? None, we think; but nevertheless we have no hope that that duty will be discharged until the matter is brought, as it soon must be, under the notice of Parliament. In five minutes an Irish member who understood the subject could, in moving the omission of the vote for the salaries of the Local Government Commissioners, do irretrievable damage to the reputation of the Board, and if the remedy for these abuses cannot be obtained in any other way, no doubt some independent Member of Parliament will be found to take the subject in hand.

Notes on Current Topics.

Contemporary Biography!

OUR attention has been directed to a recent number of a new publication devoted to contemporary biography, and as we understand that prominent and eminent members of the profession are being invited to contribute material, for the compilation of memoirs of their lives, we think it right to inform our readers of the character of the production which may be expected, should they accede to the request. The number in question professes to contain the biography of a well-known obstetric physician, and it

is composed throughout in that exuberant style of fulsome eulogy which is met with almost exclusively in puffs of cheap tailors and advertising dentists. Every now and then, however, there is a passage of what may be designated medical school phraseology, containing terms and allusions current only among those connected with hospitals; and these suggest either that the essay is written by a member of the profession—which we can hardly believe—or that the materials which the subject of the biography has been unfortunately induced to supply, have been worked up to order in to the discreditable and offensive literary mess now before us. A “life” of this kind can be of no service whatever to the intelligent and cultivated public seeking instruction or information, and could only serve to influence, in the selection of their doctor, individuals whose choice would be governed by such means as puffing advertisements. The possibility of the imputation that the subject of such a memoir was from sordid motives, conniving at its publication, is alone enough to call for the suppression of such writings, and we trust that the protest which we now make may suffice for this desirable end. We cannot believe that the publishers would persist in issuing the work were they made aware that a so-called biography, of the character of which we complain, must be offensive to any high-minded physician unfortunately made the subject of it; and if it had any effect at all upon his reputation, could only be to seriously lower him in the estimation of his professional brethren. And this effect it could assuredly have if any doubt existed that the publication was not without his sanction, and in spite of his strongly expressed protest.

The Professorship of Practical Anatomy in the Irish College of Surgeons.

THE chair vacated by the death of the late Professor Bevan will, as advertised in our columns to-day, be elected to on the 26th of January. The Council, as our readers are already aware, have decided that it shall be held only by a teacher who will devote his whole time to the duties of the professorship, not engaging in private practice, teaching, or any other extraneous employment. Several candidates have already issued circulars:—Dr. Knott, of Dublin, a distinguished former pupil of the College School, and now one of its demonstrators of anatomy, and the author of some valuable papers on anatomical subjects; Dr. T. Cranston Charles, Lecturer on Practical Physiology in St. Thomas's Hospital, brother of Dr. Charles, of Cork, and formerly a demonstrator of chemistry in Belfast College; and Dr. Edmund Ledwich, Lecturer on Anatomy in the School in which his father and uncle were so long connected. We believe also that the office will be sought by Dr. Robert Reid, Senior Demonstrator in St. Thomas's Hospital, and Anatomical Examiner in Aberdeen University.

DURING the past week 105 participating institutions in the metropolis received the amount of award from the Hospital Saturday Fund, varying from £5 to the small dispensary to nearly £400 awarded to a well-known hospital. In three cases the Distribution Committee has been obliged to withhold the cheques, as the institutions have not accepted the conditions required by the Board of delegates.

Lunatics and their Friends.

THE daily papers of the past week have contained highly sensational accounts of the escape of a lunatic from a private asylum, the full descriptive details of which once more illustrate the misjudged zeal and energy with which the friends of private lunatics will, when occasion offers, exhibit their erring sympathy with those who are placed under restraint for mental causes. This story will, in all probability, serve as the text for innumerable sermons on the injustice and impropriety of incarcerating persons who exhibit themselves in the guise of sanity at intervals while under the care of asylum officials; and we shall be told that it offers certain proof of the unsoundness of the system by which the control of our insane population is regulated. We have never hesitated to admit that Lunacy Law amendment is a desirable and even a necessary step, but we have insisted, and do still insist, that such amendments must not be in the direction of relieving the conditions under which private patients are controlled. Homicidal lunatics are notoriously a dangerous and difficult class to deal with, while, at the same time, experienced asylum superintendents are able to accord them at times an amount of liberty which removes much of the irksomeness of seclusion. Sometimes, it may be, friends who are witnesses of the apparent freedom enjoyed by such patients, assume that yet further liberty might with equal safety be accorded to them, and added to this conviction will even be the sympathy inseparable from the idea of a lengthened incarceration in the atmosphere surrounding an asylum. It is sincerely to be hoped that no unfortunate occurrence will take place to demonstrate the mistake made by those who have, in the instance referred to, been the means of effecting the escape of an asylum patient; and it is equally a matter for regret that further opportunity for “sensational mongering” should by it, have been afforded to the enemies of necessity in respect to the control of dangerous lunatics.

The Church and Scientific Progress.

WE have much pleasure in announcing that the claims of science to be respected in its efforts to promote the welfare of humanity will be formally recognised from the pulpit on Sunday next, January 8th, when a sermon in favour of legitimate vivisection will be delivered at St. Barnabas Church, Guilford Road, Stockwell, by the Rev. Richard Hill, M.A. The subject of the discourse will be “Scientific Experiments on Organic Life—a Necessity, no Sin.” The sermon will commence at 7 o'clock, and seats will be set apart for the medical faculty and those interested in the question. There will be full choral service and an anthem.

EARLY on Friday morning a policeman named Ivison found Dr. Lockerbie, of Sunderland, lying unconscious on the railway side, near to Leamside Station. His hat, money, and first-class railway ticket were found a short distance away. Dr. Lockerbie booked first-class by the 5 o'clock express from Durham to Sunderland on Thursday night, but no statement has yet been made public whether the case is one of accident or attempted suicide.

The Vacant Presidency of the Mullingar Lunatic Asylum.

THIS office, which has become vacant by the recent death of Dr. Berkeley, is the subject of active competition. The salary for a new comer will be, we believe, £400, and the allowances value for about £150 more. The succession to the office will, of course, be decided almost wholly by political influence—merit, seniority, or knowledge of the duties being of little weight in comparison to influential friends. We do hope, however, that those who have the appointment in their gift will try to find some one with the necessary political qualifications within the Irish Lunacy Department, and not as they did on a recent occasion, go afield to search for a resident medical superintendent who has never seen the inside of a lunatic asylum. We hope that the Chief Secretary has changed his views since he stated in the House of Commons that long and good service as an assistant in an Irish asylum gave no one any claim to promotion. Such a theory is unworthy of a liberal Government, and we do not suppose that Parliament will like to hear the same excuse again made for an appointment which cannot be defended on other grounds.

Workhouse Medical Discipline.

THE Workhouse Committee of the Birmingham Guardians have asked for a Local Government inquiry into certain alleged irregularities in connection with the department of the medical officer, Mr. Sampson, whom they declare to have forfeited their confidence. According to the report of a sub-committee appointed to inquire into the matter, blisters, cold shower baths, and other extreme applications have been used, under the direction of the medical officer, for the punishment of refractory patients in the infirmary, contrary to law, and without any record of these punishments being kept.

Panics in Public Halls.

THE terrible disaster at the Ring Theatre in Vienna has served once more to reopen the old question of the construction of places set apart for public entertainment, and the precautions adopted for ensuring the speedy exit of large audiences. Again and again have serious warnings been received, which, though less horrible than that contained in the Vienna catastrophe, have yet fully shown the dangerous nature of many of the theatres and halls in this country. It is significant, too, that even since the fatal panic abroad there have been several instances of the same description, fortunately unattended by loss of life, here at home. At Leeds, last week, a wild rush occurred in a music-hall, occasioned by the cry of "Fire!" and the egress of the panic-stricken crowd was prevented through the doors, which *should* have been open, being fast locked and barred, and ultimately forced from the outside. Many persons were more or less seriously injured, though none, it is said, fatally. Two other instances have been witnessed within the last few days, and in all there is the one prominent feature—that, once thoroughly alarmed and eager to escape, the dense mass of people forming the audience in any ordinary theatre has but little chance of being speedily set at liberty.

The conclusion is apparent; and until the proper authorities insist that due provision shall be made in every public hall for its immediate observance in case of need, they cannot be held to have discharged their paramount duty.

Disgraceful Exhibitions.

Too often is the public mind shocked by hearing of deplorable accidents attendant on the sensational spectacles through which it is sought to draw visitors to places of amusement; and although, as a rule, it is performers themselves who fall victims to their own foolhardiness, yet, unfortunately, this is not always the case. A miserable example of this occurred last week at Brighton, where a boy in the audience at a music-hall was instantaneously killed by the charge from a cannon poised on a dagger which a Chinese acrobat held in his mouth. The blame of this death should be laid rather on the false sentiment of the public than on the wretched being who was the immediate cause of it; for in the absence of a morbid craving after the vicious excitement such exhibitions afford, those who provide them would find no encouragement, and they would cease to exist in the detestation of every properly regulated mind. It is curious, too, that the law which insists on securing the safety, as far as possible under the circumstances, of those who take part in dangerous feats, does nothing to protect the persons who look on during the performance of them, even when they are attended with manifest risk to spectators. This end, however, would be attained if all exhibitions were prohibited which could possibly be accompanied by danger to life or limbs of artist or audience. Such a rule might, and no doubt would, have the effect of driving from the stage a large number of sensational exhibitions; but even this would be productive of good results, and would lead in time to the growth of a better and healthier public taste in the matter of recreation and amusement.

Crab Disease.

MUCH has been said lately about crab disease, but crabs are like other animals subject to a great number of diseases. Dr. Harz has made many researches on this subject which are interesting, not only to those who are considered "gourmets" but also to those who breed crabs. The disease is a parasite, due to the presence in the muscular tissue of *Diatoma cirrigerum*. From 100 to 200 have been found in one animal. Crabs suffering in this manner cease eating, become covered with spots, walk on the ends of their claws, and are stiff and clumsy. The diatoma belongs to that class of animals which undergo several changes, and does not reproduce itself until at their conclusion, not being then a perfect animal, at each stage in its life it inhabits a different animal. Crabs become subjects to them by eating dead fish.

In honour of St. Joseph Labre, the pilgrim of Boulogne-sur-Mer, who with three other saints was canonised with such magnificence and ceremonial on the 8th ult., in St. Peter's at Rome, the Catholic University of Lille has founded a chair in the Faculty of Medicine and endowed it with 100 000 francs.

Sutures in Recent Ruptures of the Perineum.

Dr. VEIT advocates the immediate union of even the lesser ruptures of the perineum. To accomplish this there is need of no elaborate armamentarium—only needles and scissors are necessary. Dr. Veit recommends to begin at the perineum with the sutures; avoid deep vaginal sutures, and all superficial ones are unnecessary. After bringing the rectal mucous membrane together, the needle is passed through the perineum behind the frenulum and carried along parallel to the rupture in the vagina to the end, where it is brought through the skin. Other deep sutures can be entered under this; superficial stitches, if necessary, are placed between the deeper ones. Chloroform is only necessary in cases that are not operated on immediately post partum.

Dr. Tanner Out-Fasted.

THE following extraordinary tale of fasting reaches us through an authentic source from India, in which an eye-witness describes the appearance of a religious mendicant of the Jain caste, who has just completed a ninety-one days' fast at Palanpur, on the last days of the penance:—The "saint," says the writer, underwent a fast of eighty-six days last year, and has been more or less accustomed to this form of infliction. When seen on the ninety-first day of the recent fast, his abdomen had so much subsided as to form the shape of a pit; the veins were much swollen, and he seemed to speak only with great effort. He was seated on a blanket in the corner, and had near him the sour water of curdled milk, which he sometimes drank. He seemed, however, to be capable of physical exertion, and up to the last day procured the curdled milk water for himself. He was all along engrossed in prayer, and held no communication with other men, except on religious topics. The man has spent his life in strict asceticism, and has denied himself all food and luxury, save what might be got from the milk water, bread, and yellow rice. His bedding consists of an ordinary blanket, and nothing more. Many Jains undergo penances in the shape of fasts and other self-inflictions, but it is said that this man's efforts in this direction are unapproached by even his most devoted co-religionists, and he has drawn to himself a large following of Sharawaks. Unlike Dr. Tanner, however, he accepts no presents and no fees.

"Notification" System for Cats.

A RECENT issue of the *New York Medical Record* comments on the fact that pet animals can carry contagion, and thus be the means of spreading fatal diseases, is not widely enough known or duly appreciated. It has heard of authentic cases in which scarlet fever was communicated from one person to another by means of a cat. Dr. Hewit, of Lake Superior, relates a somewhat similar instance in which diphtheria was communicated by the same animal, two or three of his children dying in consequence thereof. We refer to the subject in the hope that more facts bearing upon it may be communicated. These are at present scarce, but a little attention paid to the matter would, no doubt, secure much that would be of importance to comparative and preventive medicine.

A Warning to Duel Surgeons.

MR. JUSTICE CAVE, in a recent case, gave it as his opinion that a surgeon who attended a duel to prevent a man from dying was to be held equally guilty with the person who fired the shot, because, by his mere presence, he forwarded the duel.

A Universal Pharmacopœia.

THE Société de Pharmacie of Paris has resolved to print and publish the projected Universal Pharmacopœia, which had been elaborated by a special Commission at the request of the International Pharmaceutical Congress of St. Petersburg.

Bacterian Anthrax in Cattle.

MM. ARLOING, Cornevin, and Thomas have investigated the well-known immunity of adult cattle from bacterian anthrax in the infected districts. They ascribe this immunity to a gradual and infinitesimal vaccination which they have undergone, since aged cows and oxen, from districts where anthrax is not common, if brought into an infected part of the country succumb as readily as calves.

Carthago est Delenda—The Death of the Carbolic Craze!

To every thoughtful man it must be perfectly humiliating, from the scientific standpoint, to reflect on the surgical fanfare which, for the past few years agitated, not only the profession, but the public, in connection with carbolic acid, and now to read in the editorial columns of a contemporary, "we may say that the day of carbolic acid is over." . . . "The spray has been abandoned by many surgeons, and even Mr. Lister has spoken in qualified terms of its necessity; and had we to prophecy, instead of to record accomplished facts, we might venture to predict an early abandonment of this cumbersome addition to a surgeon's armamentarium." All this is precisely what all sensible men knew sufficiently well to be inevitable. But what of the great "cures" that have been accomplished by means of carbolic acid? What of the children who have first entered the "vale of tears" through its incense? What of the ephemeral reputations based on this illusory theory? What of the numerous papers which have appeared in our journals from so many incapable of forming correct judgments, both anxious as to the chance of advertising? We are getting back to where we were before the famous carbolic acid theory was propounded; but medical science cannot fail to suffer from such insensate outbreaks of surgical fashion, nor can the contempt of all intelligent members of the profession be withheld therefrom.

A TELEGRAM from New York states that small-pox is alarmingly prevalent in the west. It is supposed to have been introduced by emigrant steamers, and the western cities intend to institute quarantine against emigrants.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 40, Bombay 26, Madras 35, Paris 28, Brussels 23, Amster

dam 23, Rotterdam 24, The Hague 24, Copenhagen 19, Stockholm 14, Christiana 25, St. Petersburg 42, Berlin 24, Hamburg 21, Dresden 24, Breslau 25, Munich 29, Vienna 25, Prague 30, Buda-Pesth 33, Naples 28, Turin 20, Venice 25, Alexandria 40, New York 28, Brooklyn 22, Philadelphia 21, and Baltimore 28. No returns were received from Geneva, Rome, or Lisbon.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

SCOTCH UNIVERSITY TEACHING.—For one whole hour during the present medical session, a prominent teacher, and public edifier on everything, lectured on Lænnec, and the Apostle Paul! Fearing, as he put it, that on the previous day, he might have offended the "religious sensibilities" of some of his pupils, the next lecture was entirely devoted to justifying the association. Except that Paul is understood to have been an epileptic it is really difficult to comprehend what he has to do with the education of young men preparing for the medical profession. Such drivel as this would soon disappear with an independent examining board, and free and fair teaching.

EDINBURGH ROYAL INFIRMARY.—We learn that the dry rot has made its appearance in some of the wards of the infirmary. If this be indeed the case, either the material used for flooring is bad or sufficient ventilation has not been provided. The cost of re-flooring will be a heavy item, and must seriously affect the usefulness of the institution, which can scarcely keep its head above water as it is. The Medical School of Edinburgh is so dependent on its Royal Infirmary that the closing of any of its wards would be seriously felt.

THE COLLEGE OF PHYSICIANS AND SURGEONS OF EDINBURGH.—The rejections at these Colleges which have been gradually increasing for the last few years, reached 45 per cent. last year. Something must be wrong when so many fail. Either the examinations are more severe, or the material is very bad. Something may perhaps be said about the methods of teaching adopted at the medical schools, and for this reason we wish that the compilers of the report had also given us a table of the medical schools whence the candidates were drawn. The London College gives the medical schools where study has been carried out, and it is only fair that Edinburgh should not bear the onus of bad teaching. At any rate this is one of the "burning questions" which we hope that the Royal Commission will be able to answer.

DR. ANGUS MACDONALD.—We deeply regret to hear that this gentleman's health is not sufficiently restored to enable him to return to the more active duties of his profession.

EDINBURGH UNIVERSITY COURT.—An order of Her Majesty's Council, dated 19th December, 1881, has just been received, approving a report by the University Court of the University of Edinburgh in favour of Sir Charles Neville Thomson being permitted to retire from the Professorship of Natural History in the University on a retiring allowance in terms of the Universities (Scotland) Act, and the relative ordinances of the Commissioners for the purposes of that Act. The retirement takes effect from the date of the order in Council. An order of Her Majesty in Council, dated 19th December, 1881, has also been received, approving alterations of Ordinances No. 8 and 23, proposed by the University Court by resolution of date 11th April last, under which it is made compulsory in future upon graduates in medicine in the Uni-

versity to take the degree of Master in Surgery at the same time that they take the degree of Bachelor in Medicine, and the final fees in connection with these degrees, instead of being paid in separate sums of five guineas, will in future be paid in one sum of ten guineas, payable at the time at which the candidate comes forward to be examined in the third and fourth divisions of the examinations for graduation in medicine.

THE EDINBURGH DEATH-RATE.—For the week ending Saturday, the 24th ult., the mortality of the city, which had been only 65 in the preceding seven days, rose to 95, equivalent to an annual mortality of 22 per 1,000. This number is five above the weekly average of last year, but only one above the mortality of the corresponding week of 1880. Thirty-five deaths were of children under 5 years of age, 22 of persons over 60, and five more of persons over 80 years of age. There were 8 fatal cases of zymotic diseases. Of 133 births registered during the week 7 were illegitimate.

Correspondence.

THE HARVEIAN LECTURES ON MENSTRUATION AND ITS DERANGEMENTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—In the abstract of Dr. Meadows' first Harveian lecture, published in the *Medical Press and Circular* on Dec. 7, I find the following remarks:—"The fundus and upper part of the body of the uterus are chiefly concerned in menstruation, and a study of the anatomical structures and relations of their parts, and especially of their blood supply, must demonstrate the improbable nature of the mechanical system of uterine pathology, and the theory of strangulation of the uterus (Dr. Graily Hewitt) based upon it."

Dr. Meadows then points out that the uterine branch of the spermatic artery supplies the fundus uteri, and states that "the bulk of blood from the fundus does not descend to the cervix, but finds its way to the bulb of the ovary and thence into the spermatic vein."

In enunciating the mechanical system of uterine pathology and explaining the occurrence of uterine congestion, as will be seen at p. 33 of the third edition of my work on "Diseases of Women," the existence of the communication between the uterine and ovarian blood-vessels, is duly recognised. There is, no doubt, that the spermatic outlet has its use, but it is certainly very far indeed from being "demonstrated," as Dr. Meadows would seem to imply, that the ovarian vessels are capable of efficiently relieving the uterine circulation when there exists considerable obstruction of the great vessels of the uterus. Again, when Dr. Meadows says the bulk of blood from the fundus does not descend to the cervix, it is possible that may be approximately correct, but it must be recollected that the fundus is only a part of the body of the uterus. And I am not aware that the fundus has special properties or functions different from those of the rest of the body of the uterus. We have to deal with the whole of that part of the organ above the internal os uteri, and to consider the circumstances capable of affecting the blood current through the whole of the structures of that part. If the ovarian vessels are capable of removing congestion of the body of the uterus when the uterus is in a flexed distorted condition, how is it that they so seldom, according to my experience, succeed in doing so? and why is it that other aids and measures appear to be so often required to procure the necessary relief?

The effects of "mechanical" influences on the uterus in producing congestion have been recognised by high authorities—by Klob, as a pathologist, by Gaillard Thomas, as a clinical observer. That distortion of the uterus, known as flexion, is a common accompaniment and cause of congestion of the uterus. A physical compression is present at the centre of the uterus, the effects of which the ovarian outlet is incapable of obviating to any appreciable extent, when this compression exists in a marked degree.

Yours, &c.,

GRAILY HEWITT.

Berkeley Square, London, W.

THE ALLEGED CONSPIRACY AT SUNDERLAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the statements which have appeared in the *Lancet* and other journals, with regard to my evidence in this case are grossly inaccurate, I ask you in accordance with your well known impartiality, to allow me to contradict the same, and to say that I never said I had applied the electric test for Sir William Jenner. What I said was that "I had dealt with electricity under Sir William Jenner and other distinguished men while holding some appointments as clinical clerk, &c., at University College Hospital." "That I was associated with Sir William Jenner as clinical clerk, but had no other association with him." "That I acquired the commencement of my galvanic knowledge at University College Hospital."

To prove that I acted as Clinical Clerk I subjoin the following testimonial :—

[COPY.]

63 Brook Street, Grosvenor Square,
Nov. 19, 1877.

I have great pleasure in stating that Mr. H. R. Dale is well known to me from having been my clinical clerk at University Hospital. I am satisfied not only from the honours Mr. Dale obtained at the College, but from my personal observation of him in the wards of the hospital, that he is highly qualified to practise his profession. He discharged the duties of Clinical Clerk to me to my entire satisfaction, and I believe he will prove a valuable Assistant Medical Officer to any large public institution.

(Signed) WILLIAM JENNER, M.D.

Furthermore, I most distinctly said in my evidence that I had used the electric test for malingers in two cases only, when I was Assistant Medical Officer at the Infirmary, St. George's in the East, London.

As I have entered into my recognisances to give evidence on behalf of Michael M'Mann at the forthcoming Assizes, this *ungrounded attack* on my veracity by the *Lancet* is naturally very painful and injurious to me. I trust therefore in the interests of truth and justice you will be kind enough to insert this correction and refutation.

I am, sir, yours truly,

HENRY RIDLEY DALE, M.R.C.S.,
L.R.C.P.Ed., &c.

10 Nicholson Street, Sunderland.
Dec 24, 1881.

ANTI-VIVISECTION FANATICISM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to the article under the above heading in the *Medical Press and Circular* of this date, will you permit me to ask for an enumeration of the particular undisputed improvements in medicine, surgery, and therapeutics that have resulted from "vivisection?"

The article alluded to contains the expressions, "scientific workers" and "scientists." But neither appears to have reference actually to benefit to mankind through advance in any branch of medical knowledge obtained, or likely to be obtained, by the means indicated. I merely ask for information.

Yours, very truly,

14th December, 1881.

INQUIRER.

NOTES ON VACCINATION AND RE-VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I read with much interest in your number for 2nd ult., Dr. Berry's "Note on vaccination and re-vaccination," in which I think he shows clearly with regard to the former, that three trials are not enough to establish insusceptibility of vaccine infection, but I cannot coincide in his views on the latter. I am a vaccinator of long standing, and have from the first, paid attention to the controversy as to the necessity of re-vaccination in all cases, or, in other words, whether the protection conferred by vaccination is merely temporary. In an epidemic of variola many years ago, I re-vaccinated myself and all the other adults of my family, all presenting characteristic cicatrices of successful vaccination

performed in infancy, also others similarly circumstanced, and anxious on the subject. In all of us a "pock" produced, which, by the lay folk, was pronounced to be a "very fine" one, being large and accompanied by much irritation, swelling, and painful induration, involving in most of the cases, the axillary glands, but in no instance could I recognise the existence of a genuine vaccine vesicle. These *pustules*, as I think they should be called, ran a more rapid course than the vaccine vesicle; the local irritation generally began before the third day, was accompanied by intense itching and was sooner matured, the combined fluid becoming sooner opaque, they did not leave the characteristic cicatrix of successful primary vaccination. It is true that neither I, though constantly brought in contact at the time with variola, took it, nor did any of the others experimented on; but then, neither did any of the people in a large district on whom the primary operation had been successfully performed in infancy, though exposed to the epidemic influence all the time of its prevalence.

Let me not, in what I have said, be understood to depreciate the value of re-vaccination. No one with the Homerton report of 1877 before him could do so; and my opinion is, that even the spurious pock which I have been considering may, and ought to be called "successful," in the sense of having demonstrated the security from variolous infection enjoyed by those in whom they have been produced. Dr. Berry does not make any mention of having used Bryce's test in those cases. If he has not done so, I should suggest that he should in any future researches he may make, do so in this way. When the presence of fluid in the so-called vesicle is ascertained, and before it has become opaque (say before the eighth day) in the arm of the re-vaccinated subject who presents the characteristic cicatrix of a successful primary vaccination, insert it into the other arm and observe whether it produces, at the usual time, the typical circular, semi-transparent, pearl-coloured vesicle, depressed in the centre, over-hanging at the circumference, confined to the place of puncture or scarification, surrounded with a red areola, concreting into a hard dark-coloured scab after the twelfth day, all the while running in a course parallel with the first. Let him treat the arm of an unvaccinated infant in the same way, and observe if it produces an affection running a similar course. This experiment will be crucial. If both the results answer the conditions above stated, then, and *not till* then, may the re-vaccination, in my humble judgment be considered "successful" in his sense of the term.

Yours, &c.,

EDMUND P. SHARKEY, A.M., M.D. Dub.

Literature.

A TREATISE ON THERAPEUTICS. (a)

THE present work is a portion of "Low's Library of Standard Medical Authors;" and, if the series continues up to the present mark, we feel that it will be a very valuable addition to medical literature. We have already in the English language a large number of excellent works upon materia medica and pharmacy; but it is only in recent years that the science of therapeutics has received here the amount of attention which its transcendent importance deserves, and that has been bestowed upon it by our continental *confères*. We are, for this reason, gratified to see a work of the supreme position of Trousseau's, and one which has stood the test of nine editions, presented in a vernacular dress, useful to that large class of medical men who prefer to read a medical teacher in their native language. The French edition of Trousseau is a much larger affair than even the three volumes now before us; inasmuch, as it embraces the materia medica and prescriptions which, on the present occasion, are omitted in order to reduce the publication within practicable limits. The author dashes at once *in medias res*; and, without any preface, at once begins with iron and other reconstituent remedies, from which he turns to astringents, alteratives, and irritants. He next proceeds to antiphlogistic

(a) "A Treatise on Therapeutics." Translated by D. T. Lincoln, M.D., from the French of A. Trousseau, and of H. Pidoux. Ninth Edition, Revised, with the assistance of Constantine Paul. 3 vols., 8vo. Pp. 970. London: Sampson, Low, Marston, Searle, and Rivington. 1881.

treatment; to evacuants, including emetics and cathartics and to excitomotor, and narcotic medicines. The next portion treats, in the most exhaustive manner, of anæsthetics, anti-spasmodics, and neurosthenic tonics. He next takes up the department of excitants, and next that of sedatives, and contra-stimulants, and concludes with a disquisition on anthelemintic remedies.

The tendency of the whole work may be described as intensely clinical and practical; and it would be simply impossible for any physician, however well educated, to peruse these volumes without feeling that he had added to his stock of knowledge, useful for the purposes of everyday working life; in fact, the same might be almost said for the reading of any individual chapter. The work has been, in one shape or another, before the French profession since the year 1836, and has since undergone the constant revision and improvement, not only of its illustrious author, but of his eminent *collaborateurs*, MM. Pidoux and Paul; and we will merely say that it does honour to its distinguished parentage. Nor in these remarks are we to omit a due meed of praise to its American translator, who has performed his part in a way worthy of the work he was translating. We regret that the publishers did not see their way to a fourth volume, for we should have liked to have had the details of the physiological action of the drugs; for the present, however, Ringer and Bartholow will fill up the gap for English readers. For the same reason we should have welcomed the articles upon magnetism and electricity, and on hydro-therapeutics, all most important subjects; but perhaps there is a good time coming when the publishers will produce a supplement containing all these details. The typography of the book is excellent and correct; the only error worth mentioning, that we have met with, being on page 24, where the formula of Rodet's prophylactic solution for venereal disease, "citric" acid is mentioned by an obvious misprint for nitric. We heartily commend this treatise to the hospital physician, the practitioner, and the student, as a thesaurus of sound practical medicine which will never fail them either as a dictionary of reference, or a means of continual study. The metric doses of the various medicines are given (how long are we to be without the metric system in our Pharmacopœia and prescriptions?), but the respective *avoirdupois* equivalents, are, for the present, annexed.

THE HERESIES OF MEDICINE. (a)

DR. SMYTHE has put forth a readable, forcible, and logical work, the chief aim and intention of which is to expose the absurdities of the homœopathic principle of medicine. This he does in the most effectual manner; not by angry declamation, but by a method of calm analysis, the results of which must prove convincing to all but unreasoning fanatics, or blindly prejudiced followers of the illusion hunting Hahnemann. We could wish every modern homœopath might learn as much of the nonsense he champions in his ignorance, as this little book would teach him; but we unfortunately know too well the school is not amenable to enlightenment on its own weaknesses. Nevertheless, Dr. Smythe's book will be not devoid of good consequences: it is rendered further valuable by a historical, but necessarily brief survey of the rise and growth of medical science, and is bright and readable throughout. We heartily recommend it.

DEAFMUTISM (b).

It is some years since any comprehensive work on Deaf-mutism appeared. In the meanwhile as the study of Otolology has advanced, the question of the education of those whose afflictions are beyond the aid of the aural surgeon has received more attention. Amongst those who have worked in this direction are the author and the translator of the work now before us. Dr. Hartmann is evidently thoroughly well acquainted with the subject, and has arranged his material in a very orderly and methodical manner. Commencing with the medical and statistical aspects of the question, the anatomical changes on which deafmutism is based, he then

considers the various kinds of sign-language, and the methods of education of the deaf mutes. The author is strongly in favour of the method of instruction by lip reading and articulation, and gives full instructions for its practice. He then considers what has been achieved, speaks of the treatment of deafmutes after leaving school, and concludes with a number of statistical tables. From one of these it appears, that of the European countries Switzerland shows the largest proportion of deaf mutes to population, viz., 24.52 among 10,000, the Netherlands the smallest, 3.35 in 10,000, while in Great Britain and Ireland the proportion is 5.70, in Germany 9.66, in France 6.26. There are many points in this work on which we could dilate; we have read it with much pleasure, and hope it may be instrumental in spreading the use of the lip-reading method of instruction of the deaf and dumb. Those of our readers who attended in the section of Otolology at the International Medical Congress will remember a very excellent paper read on the subject by Mr. Kenny, in which the cause of the deaf mutes was most eloquently pleaded, and the deficient means of instruction provided in Great Britain strongly commented on. There is certainly no doubt from Hartmann's statistics that this country is behind many others in the provision made for the education of deafmutes, and we sincerely hope the publication of this work will help in remedying the defect. Some praise is due to the translator for the manner in which he has rendered the work in easy, flowing readable English. Dr. Cassells is favourably and widely known as an energetic worker in otology, and the production of this book will no doubt add to his reputation. To all who practice aural surgery, or who are otherwise interested in the amelioration of the condition of a large number of our afflicted fellow creatures, we can most heartily recommend this work as being full of information, well compiled and agreeable reading.

THE HARROGATE WATER. (a)

THE Harrogate of the present day contrasts favourably and conspicuously with the "Harrigate" of 1790, as described by Dr. Tobias Smollett in "Humphrey Clinker." The place is no longer "a wild common, bare and bleak, without tree or shrub, where the people, who come to drink the water, are crowded together in paltry inns," but has now grown into a well-watered, well-drained, health resort, where the spacious hotels and lodging-houses easily find room for 60,000 visitors every year. No wonder that many treatises have been written on the salubrity of Harrogate, and the virtues of its medicinal waters. The recent work of Dr. Oliver is calculated fully to sustain the reputation of Harrogate, and after hearing how dry and pure the air, how small the rainfall, and how eminently curative the place appears to be for apparently every known chronic disease, we look with special interest at page 36 to the list of complaints that are not likely to derive benefit from a visit to Harrogate.

Chronic pulmonary disease, of tubercular rather than strumous nature, with fever and progressive local change, it seems is not likely to do well at Harrogate. Probably not, for the best place for such a patient is his own home.

In chronic pulmonary disease, of apparently non-tubercular character, we have observed very marked benefit to result from a summer at Harrogate in more than one instance. The patients acquire appetite, and digest their food and cod-liver oil well under the influence of the dry bracing air.

Dr. Oliver's observations on the Harrogate waters are interesting. The waters are powerful, and not ones to be played with. We have ourselves seen most unmistakable mischief, with blood-spitting, brought on by the injudicious use of the sulphur water.

Tables of the chemical composition of all the Harrogate waters are given with much detail, the strength of the springs being contrasted with that of many continental sources. A good deal of stress is laid by Dr. Oliver on the presence of barium chloride in the old sulphur well, and this salt is held to act as a neuro-vascular tonic and anti-strumous agent. When the purgative action of the sulphur water is maintained, the author has repeatedly observed, and measured by Hawksley's sphygmometer, a decided increase of intra-arterial

(b) "Deafmutism and the Education of Deafmutes by Lip-reading and Articulation." By Dr. A. Hartmann of Berlin, translated and enlarged by J. Patterson Cassells, M.D., L.R.C.S., F.F.P.S., &c. London: Baillière, Tindall and Cox. 1881. P.p. 224.

(a) "The Harrogate Waters. Data, Chemical and Therapeutical, with Notes on the Climate of Harrogate." By George Oliver, M.D. Lond., M.R.C.P. London: H. K. Lewis. 1881. P.p. 224.

pressure. Correctly, as we judge, Dr. Oliver refers this improvement in the circulation to the depurative action of the sulphur water on the blood, but he evidently believes in chloride of barium as a stimulant to the heart and blood-vessels. We happen to have employed chloride of barium internally in cases of strumous enlargement of the glands in children, but have failed to recognise any curative property in the salt.

The sections on the therapeutical uses of the Harrogate waters are short and eminently practical. We quote the following, which seems to show on the author's part an acute perception of just the kind of cases that often derive very marked benefit from a judicious method of water-drinking. "Chronic ailments, unassociated with wasting organic diseases, derive most benefit from Harrogate and its waters; such as struma, gout, rheumatism, skin diseases, anæmia and relaxation of tissue, portal congestion, &c. Among these diseases the treatment, when periodically resorted to, is frequently observed to be of great value in such cases as have settled into that obdurate state which cannot be impressed by ordinary remedies; cases in which the pathological condition of the tissues reminds one of the compacted soil around the roots of plants, which bars out the life-giving influences of Nature, but when broken up permits them again to diffuse health and vigour throughout the vegetable tissues."

We may just say in conclusion that Dr. Oliver's book is addressed to the members of the medical profession. The whole matter and style of the work fully bears out this dedication for the book is one that is above the scope of most non-professional readers while it is full of practical interest to working members of the profession.

CONSUMPTION. (a)

In the present work of seventy-eight pages, we have the causes, nature, and therapeutical treatment of pulmonary consumption placed almost at a glance before us. The author has evidently read up pretty widely on his subject, as his abundant quotations from various writers amply testify. The cause of pulmonary consumption appears to be due to an undue action or excessive influence of atmospheric oxygen; a theory by no means novel, and one that has been thought to explain the curative action of cod-liver oil in phthisis, inasmuch as the carbon of the oil combining with oxygen protects the tissues of the body from too rapid oxidation. This has been described by Dr. Walshe as "the pure oleaginous view; whether the oil acts by affording a material to be oxidised, and so sparing the oxidisable tissues," (b) whether this is the way the oil acts still remains matter of conjecture.

Considerable prominence is given to Dr. J. F. Churchill's opinion that the tubercular diathesis is owing to a decrease in the system of the phosphorus which it contains in an oxidisable form. The author holds this view to be "undoubtedly correct as one of the conditions existing in consumption; but it is not a cause."

We should have liked to have seen more clinical evidence adduced in support of the theoretical considerations put forth by Mr. de Lacy Evans. The work is ingenious and interesting. As to the results that may follow on practically carrying out its principles here every observer must judge for himself.

GUIDE TO TREFRIW, AND THE VALE OF CONWAY SPA. (c)

TREFRIW (pronounced Trêvroo) is a village on the western bank of the river Conway, on the road from Conway to Bellwasy-coed and Llanrwst. The small work of Dr. Hayward gives account of the climate and mineral springs of Trefriw. The waters are of the strong chalybeate class, and a wineglassful at the spring is reckoned a very full dose of

(a) "Consumption: a Re-investigation of its Causes. Showing it to Arise chiefly from an Excessive Action of Atmospheric Oxygen. Its Dietetic, Climatic, and Therapeutical Treatment." By C. W. de Lacy Evans, M.R.C.S. Eng. London: Baillière, Tindall, and Cox. 1881. Pp. 78.

(b) Walshe. "On Diseases of Lungs." P. 485.

(c) "Guide to Trefriw, and the Vale of Conway Spa." By John W. Hayward, M.D., M.R.C.S., L.S.A. Third Edition. Liverpool: Adam Holden. London: Simpkin and Marshall, 1881. Pp. 77.

the No. 1 water, for this will contain nearly nine grains of crystallised sulphate of iron. The place appears to be growing in repute, but it seems clear that the waters should only be taken by an invalid who is under strict medical supervision.

THE CLIMATE OF THE UNDERCLIFF. (a)

THE forty years' meteorological observations on the climate of the Isle of Wight Undercliff, recorded in this book by Dr. Whitehead, extend over the years from 1840 to 1879 inclusive, and were commenced by the late Dr. Martin, of Ventnor. These tables comprise registrations of temperature, atmospheric pressure, prevailing winds, humidity, rainfall, ozonic state of the air, and all matters sufficient to satisfy the most fidgetty and nervous of invalids to his or her heart's content. The first seven pages of Dr. Whitehead's introductory remarks deduce practical inferences from the tables, and are well worth study. We learn, for example, that the temperature of the Undercliff during the spring months does not increase in the same proportion as that of Greenwich, but that the warmth is continued well into the autumn. So far as our own practical experience serves, we have usually found pulmonary invalids to delight in the autumn climate of Ventnor, while in the early spring a preference is often given to Bourne-mouth or Torquay, as being places less exposed to the east wind.

Dr. Whitehead's book is well got up, and ought to find a place in the library of all who are interested in the English health resorts, as a useful book of reference.

DAVOS PLATZ. (b)

DR. ALFRED WISE'S work on Davos Platz is a small volume containing at its close weather reports for 1880, and tables of sun-radiation, observed by F. Bedford, F.R.S. in 1876-77. The weather reports read as far from encouraging for an invalid who, after a wearying and expensive journey has at last reached the much-belauded Davos—"Raining; Foggy overhead," "Wind north-east," "Drizzle continues," "Snowing most of the day." Such appears to some extent to be the condition out of doors during the autumn, and a condition that will probably render it desirable for the invalid to remain a prisoner in his hotel. Hotel accommodation at Davos (says Dr. Wise) has greatly improved of late years. This is cheering, though we fear that a preceding paragraph may slightly unsettle the nerves of one who, when abroad, is continually haunted by fears of water poisoning or bad drainage, and an attack of typhoid fever as a by no means very remote contingency. The paragraph reads, "A small population in a healthy locality with the oxidising results of the air, the absorbent nature of the soil, and antiseptic powers of a low temperature, may certainly trifle to an alarming extent in sanitary matters." Dr. Wise has doubtless employed his nose as well as his eyes, and the above statement is suggestive.

The remarks on the therapeutical effects of cold are excellent, and in a few words show the why and the wherefore of a dry cold air being so eminently beneficial to a large class of consumptive patients.

The drawbacks of Davos are faithfully and impartially set before the reader by Dr. Wise. Truly does he say that there appears to be a limit, difficult of definition, where cold resorts cease to be of value, as "change," and even become dangerous. Dr. Wise also, we gather, considers a well-sited home to be of all places the best for cases of advanced consumption. Here we most thoroughly support him. We know how very strongly experienced ship surgeons deprecate the sending of advanced invalids on a long voyage, and yet for many cases of established, but not advanced, pulmonary consumption, the curative effect of a voyage to

(a) "The Climate of the Undercliff, Isle of Wight, as Deduced from Forty Years' Consecutive Meteorological Observations." By J. L. Whitehead, M.D. Pp. 46. J. and A. Churchill, New Burlington Street.

(b) "Davos Platz and the Effects of High Altitudes on Phthisis." By Alfred Wise, M.D., L.R.C.P.; Physician to the Infirmary for Consumption, Margaret Street, &c. Pp. 74. J. and A. Churchill, New Burlington Street.

Australia and back is unsurpassed by any result that can be obtained at the land health resorts. It will not take long for any one to read Dr. Wise's book through, and we should advise all contemplating a visit to Davos to get the work and study it well.

THE USE OF THE LARYNGOSCOPE. (a)

ANY work which has for its aim the extension among general practitioners of the uses of such aids to diagnosis and treatment as the laryngoscope deserves to be examined in a favourable spirit. As far as it goes the work before us is deserving of some commendation. The construction and method of use of this instrument are fairly well described in clear and readable language. The illustrations are apt and suitable, and give a good idea of the subjects they are intended to represent. In most of his directions the author follows the teaching of Dr. Morell Mackenzie. Chapter IV, on "Cases in which the Laryngoscope should be Used," might advantageously have been made fuller. In the chapter on Rhinoscopy, fig. 14 is described as representing the "view with the rhinoscope (right side)." This should have been left side, and the misprint is unfortunate, as it is likely to occasion the beginner in the art some confusion. Tyros almost always find it difficult to understand that there is no lateral reversal in either the rhinoscopic or laryngoscopic image, and a drawing intended to be a guide which leads them wrong is a serious blot upon a book. Otherwise, Mr. Holmes has produced a creditable little work, and one which will doubtless be of use to students and practitioners.

WHAT TO DO IN CASES OF POISONING. (b)

THIS little brochure will be of much use to the student and junior practitioner. It starts with a list and description of the remedies contained in the "antidote bag," and then gives all the ordinary poisons and their appropriate remedies. Some rather innocent substances are given, e.g., bismuth, which is stated to be poisonous if adulterated with arsenic, an observation which might apply to any article whatever. As a whole, however, the work is well and clearly done, and will be most valuable for rapid reference in cases of emergency.

Obituary.

DR. REUBEN J. HARVEY, OF DUBLIN.

THE losses of medicine are more striking than its triumphs. It is our sad duty to record the death of one of its chief pioneers in the path of progress—one of its most earnest workers in the discovery and teaching of scientific truth. The removal from our midst of Reuben Harvey is to our profession nothing short of a national misfortune. It is not merely that he was a man of remarkable ability, nor that he showed a singular devotion to the work he felt himself called to, nor even that as a practical physician his hospital statistics proved his skill and success in the treatment of disease. These facts alone do not account for the strong impress his life, short though it was, left upon all around him. In addition to all these attributes, there was a force of character peculiarly his own, which, though shrouded by a retiring disposition, imperceptibly asserted itself, and awoke in those with whom he came in contact a reverence, if not in some degree, a reflection of its qualities.

After leaving school, he first entered the Queen's College, Cork, of which his father, Dr. J. R. Harvey, who now survives him, was professor of midwifery. Shortly afterwards he entered Trinity College, Dublin,

where his attainments in pure mathematics soon brought him into notice. During his arts course he repeatedly gained first honours. In 1865 he won a science scholarship; and in the year following he obtained his degree by senior moderatorship and gold medal. In medicine his training was equally thorough. After obtaining the first medical scholarship, and the degree of M.B., he studied in the schools of Vienna and Wurzburg, under Professors Stricker and Recklinghausen. It was in the Continental schools that he learned to interest himself practically in the physiological and pathological subjects, which was afterwards the chief field of his research. On his return he was immediately appointed a demonstrator of anatomy in the Trinity College School; and shortly afterwards he was appointed a lecturer on physiology in the Carmichael School of Medicine, along with Dr. Gerald Yeo (now of King's College). This chair he held till the period of his death, and it was with the discharge of his duties in connection with it that his mental and moral qualities were most strongly brought into light. He held that the standard of physiological teaching should not be a second-hand compilation of statements, but a training to individual observation and deduction; that it should be not a burden on the memory, but a discipline and a method. He accordingly set himself to lift it out of its position, as a course to be perfunctorily delivered, and to make it the ever-growing study of the laws of life and function. How he succeeded, in spite of manifold obstacles, hundreds of his pupils can testify. In 1875 he was appointed assistant-physician and pathologist to the Richmond, Whitworth, and Hardwicke Hospitals; and about the same time he was elected to the post of assistant-physician to Cork Street Fever Hospital. A year later he succeeded to the physicianship of the latter institution, and through the many epidemics in which Dublin has a sad pre-eminence, he laboured faithfully and successfully till, in the wards he loved so well, he won the highest guerdon of a life like his—a life that knew no selfishness—death in the discharge of his duty.

Though busied with two hospital appointments, and the teaching of both theoretical and practical physiological classes, he made time for a large share of original work. Much, unfortunately, was never published; but in addition to papers read before medical societies, and an extensive series of researches on staining re-agents, the following contributions have happily been preserved in a permanent form:—"On the Histology of Tendon" (*Irish Hospital Gazette*, 1873); "Ueber die Zwischensubstanz der Hoden" (*Centralblatt*, 1875); on the Mode of Occurrence of Compensatory Emphysema" (Medical Society, K. & Q. C. P., 1879); "On the Cause of the Dicrotic Wave in the Pulse, and on Cardiographic Tracings" (British Medical Association, 1879).

The sketch would be incomplete if it omitted mention of his efforts to improve medical education in this Kingdom. His nature made him detest pretences, and against "cramming" he fought with all his might. With broad views on the scope of knowledge that should be required of the student, he struggled persistently, that the knowledge should be thorough, that it should be honestly and systematically acquired, and that it should be a training ground for the acquisition or elucidation of further truth.

SICK LEAVE, INDIA.

THE Secretary of State for India, it is announced, has placed a restriction on the period of all sick-leaves out of India granted by the Indian Government. Heretofore the period has been two years in almost all cases; in future, only one year will be granted under any of the furlough rules now in force on medical certificate, and the question of its extension will be left to the decision of the standing Medical Board at the India-Office.

IRISH POOR LAW SUPERANNUATION.

We understand that a meeting of Union Officers in Ireland has been convened to meet in Dublin on the 13th of January, for the purpose of considering the prospects of obtaining an improved method of superannuation from that now in force. The meeting is convened by non-medical Union Officers, but having made enquiry we have learned that the presences and advice of all Union Officers is hoped for, and that medical officers of Dispensaries and Work-houses are fully entitled to attend.

Ament this conference—which is, of course, quite reasonable and proper under the circumstances,—we would say that nothing would more certainly defeat the object which both medical and non-medical officers have in view, than a collision between the two classes on the question of superannuation. On the one hand the medical officers have no other purpose than to advocate what is fair for the non-medical officers as well as themselves. On the other hand it is quite clear that the non-medical officers can gain nothing and will lose the benefit of a precedent if, without advancing their own cause, they impede that of the doctors. We would be glad to think that it is possible to induce Parliament to grant compulsory superannuation for all Union Officers, but we fear no such hope can be entertained, and it certainly would be a mistake to engage in a game of “dog in the manger” in reference to such a subject.

Novelties.

A NEW UTERO-VAGINAL SYRINGE.

A NEW instrument which seems to have some points of value has recently been brought before the profession in America, by Parke, Davis, & Co., of Detroit. It is the invention of Dr. H. T. Chamberlain, of Rochester, N.Y., and its construction will be readily understood from the following illustration.

The instrument shown in the cut is constructed as follows, viz.: The vaginal tube is six inches in length; the surface is divided into ten longitudinal grooves one-eighth of an inch deep, with an orifice at the termination of each at the base of the dome for a reverse stream. In the dome are orifices for direct and diverging streams. Being nearly an inch in diameter, it acts as a “repositor” in prolapsus uteri. It presses the organ up to its normal position, at the same time distending the folds, by gently rotating the tube while the liquid is being injected. The grooves detach the tenacious mucus that adheres to the

membrane, and the reverse streams passing down between the instrument and surface of the vagina, effectually removes it. Dr. Chamberlain says that by this two important results are attained, viz.: The unhealthy secretions are removed and all injury arising therefrom obviated. The mucous membrane of the vagina and cervix uteri are effectually cleansed. If disease exist, medicine may now be directly and thoroughly applied to the affected part.

AN examination of candidates for Commissions in the medical department of Her Majesty's Army will be held at the London University, Burlington Gardens, on the 20th February next, and following days, at 10 o'clock a.m.

PASS LISTS.

Royal College of Physicians of London.—The following candidates were admitted Licentiates on December 27, 1881:—

- | | |
|----------------------------------|-------------------------------|
| Alkins, William H., M.B. Toronto | Gilder, Sherrington E. A. |
| Allen, William A., M.B., Toronto | Hawksworth, Herbert |
| Benoly, N., M.D., Wurzburg | Morton, Charles Alexand |
| Casson, Harwood | Pilkington, Frederick William |
| Cowan, Frederick Samuel | Puddicombe, Francis Morgan |
| Dunmere, Howard Howse | Thornton, Bertram |
| Edmondson, W. C., M.B., Toronto | Wallace, Alfred Cyprian |
| Foxwell, William Arthur | Warner, Percy |

University of Dublin.—The following degrees have been conferred during the past month:—

- | | |
|------------------------------|------------------------------|
| <i>Bachelor in Medicine.</i> | |
| Archer, Arthur Montfort | Johnston, Alex. Richmond |
| Gillespie, Thomas Richard | Newell, Francis Thorpe Forte |
| Henry, William | Scott, William Sidney Jebb |
| | Wilson, Edmund B. |

- | | |
|-----------------------------|----------------------|
| <i>Bachelor in Surgery.</i> | |
| Archer, Arthur Montfort | Pope, Henry Brougham |
| Johnston, Alex. Richmond | Wilson, Edmund B. |

- | | |
|----------------------------|---------------------------|
| <i>Doctor in Medicine.</i> | |
| Gabbett, Henry S. | Studdert, Richard Charles |
| Line, Wm. Henry | White, Richard Dormer |

College of Physicians in Ireland.—At the December Examinations the following obtained the Licences in Medicine and Midwifery of the College:—

- | | |
|-------------------------------|-------------------------|
| Browne, Danby | Jacob, Wm. Gardiner |
| Cahill, Thos. Emonde | Magner, Thomas |
| Coolican, John Patrick Joseph | Murphy, Patrick Joseph |
| Elderton, Frederick Dundas | Trotton, Maurice Joseph |
| | Wilkin, Lotus Ralph |

The following Licentiates have been admitted Members:—

Gunn, Christopher	Horne, Andrew J.	M'Laren, Agnes
-------------------	------------------	----------------

NOTICES TO CORRESPONDENTS.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

INDIAN MEDICAL SERVICE.—Candidates for this department of the Imperial services are reminded by advertisement in another column that the next examination will be held on the 20th February. Applications must reach the India Office at least a fortnight before this date.

DR. PEARSE (Plymouth).—Your communication will probably appear in our next. Thanks for a sight of the letter from India.

B. E. T.—The argument sounds very well in theory until brought face to face with facts, when it vanishes as quickly as most of the chimeras of the anti-vaccinationists. It, moreover, has not even the merit of novelty, its untenableness having been exposed thrice previously to our knowledge. As a rule, it is unwise for medical men to attend meetings of the kind, as their presence gives occasion for reports of secret acquiescence, although the opposite be the case. You did well, however, to stand up in defence of the profession, and your views in particular, when appealed to.

MR. MURRAY (Edinburgh).—The facts are interesting and instructive; we shall utilise them in an early number.

MR. C. H. B.—Certain information has come under our notice lately which would lead us to take an opposite view of the case; under the circumstances we would counsel you to wait, as the law is a very ticklish instrument to set in motion, and even if you win it proves costly.

MR. WALDIE will find full particulars on reference to our last “Student's Number,” Sept. 20th.

AN ANXIOUS ONE.—We would advise cutting short your anxiety by at once consulting a qualified practitioner. The fellow you are now “under” is a quack of the worst description; you will find something very unavourable about him in a little book entitled “Revelations of Quacks and Quackery.”

MR. T.—We cannot sufficiently thank you for all your kind expressions. Be assured we cordially reciprocate the good wishes, and that we are only too delighted to have been the means of extending the measure of your enjoyment.

DISPENSARY CONSULTATIONS—CONSTABULARY ATTENDANCE.—W. H. asks: 1. Being called in by a neighbouring dispensary doctor to assist in a midwifery case a distance of nine miles, and, as the case was red-ticket, an order having been procured from the relieving officer, when the matter was referred to the dispensary committee of the district in which the woman resided, they only recommended the board of guardians to pay me one guinea. I have not yet submitted to this recommendation, and I wish to know whether I have any legal means of enforcing my claim for £2 2s., the usual consulting fee? 2. Is the medical officer of constabulary obliged to attend the wife, children, and other relations of the sub-inspector who may be with him, without being fed; and, if so, is he obliged to go at any moment he may be sent for without any real urgency in the case?

[1. You can readily recover your fee from the guardians, but

must be prepared to prove before the magistrates (a) that you were duly called by the relieving officer, (b) that the fee you claim is reasonable, considering the time and place of your attendance and the services rendered. To establish this latter point, you must produce one or more medical witnesses to swear that the fee claimed is usual and proper. All depends on this, for your claim is a matter of simple contract and not of law, and—if not satisfied on this point—the magistrates may award any sum they please. Nevertheless, we think there cannot be a doubt that you are fairly entitled to £2 2s., and can easily recover that fee. 2. Certainly not, you must attend "all members of the Royal Irish Constabulary and the wives and families of the men." The non-liability to attend families of officers is admitted by the authorities.—See "Irish Medical Directory," 1881, page 332.—ED.]

GALVANO-PUNCTURE IN ANEURISM.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—In the number of your Journal for Dec. 14th, 1881, you refer to a very interesting case of "Galvano-puncture in Aneurism," which you find reported in the *New York Medical Record* for November 24th last. I beg leave to inform you that the name of the operator is incorrectly given in your notice—the error, probably, originating in the American journal.

The correct name is Dr. Richard Cannon, a very accomplished surgeon, son of Edward Cannon, Esq., Kemilworth Square, Dublin, and now practising successfully in Chili.

Faithfully yours,

S. M. MACSWINEY.

38 York Street, Dec. 16th, 1881.

IRISH LUNATIC ASYLUM APPOINTMENTS.—J. D. K. says: Let me know the necessary qualifications and age limitation to obtain the appointment of medical superintendent to a lunatic asylum, as also the person to whom application should be made.

[1. The appointment is nominally with the Lord-Lieutenant, actually with the Irish Government, usually through the influence of the county members. 2. The qualifications are diplomas as a physician and surgeon and one in midwifery. No limit of age is set down in the regulations.—See "Irish Medical Directory," page 300.—ED.]

MR. H. R. C.—Gant's "Guide to the Examinations of the College of Surgeons" will convey to your mind an excellent idea of what is required.

"JERRY" BUILDING.

Being a sure Recipe for Rheumatism Fever, Cold, etc.

FIRST buy your ground; to be, of course, the cheapest lot you've seen;

For choice, an ancient brickfield, or where once the ground has been

Dug out for sand or gravel, with the holes all newly fill'd
With rubbish from the dust-heap, such as cats, untimely kill'd,
Old bottles, cabbage-stalks, and tins,—to name them all is hard,—
Though you'll find the chief components in the dust-bin in the yard.

Now, ere proceeding further, it is best to first procure
A copy of the by-laws for the district; then be sure
To spend each leisure moment trying how to circumvent,
Within the law, if possible, their very plain intent.

Next excavate, put concrete in,—here 1 to 12 will do,
Then start your footings,—say bricks! they're not exposed to view.
For mortar, take a little lime, some sand, some ash, much earth;
Be care, when mix'd together, of the latter you've no dearth.

You'll connect the drains, of course, at the end next house, and thence
Run them a few feet underground and leave, to save expense;
You'll fix your cistern where you choose, and take the utmost care
That afterwards it can't be reach'd for cleansing or repair.

You'll let the same supply the bath, the closet,—all the lot,—
Take waste and soil pipe down in one to where the drains are not.
But finish your fronts with care, with stone dressings, bays, and
strings;

Inside with showy paper, deep cornice, and such like things.
And mortgage it floor by floor after the manner of old,
And put up a bill when finish'd, "House to be let or sold."
Then when you've secured a victim,—a tenant he's call'd by you,—
You'll migrate with a peaceful heart to "fresh fields and pastures
new."
—*The Builder.*

ORIGINAL COMMUNICATIONS.—The following have been received since our last number:—

"On Imperfect Involution of the Uterus and its Consequences," by Lombe Atthill, M.D.

"A Short Retrospect of the Sanitation of former years as contrasted with that of the Present," by Frank J. Davys, B.A.

Clinical Lecture "On the Treatment of Tetanus," by Lambert H. Ormsby, F.R.C.S.

"Lucan Spa," by G. S. B. Stoney, L.R.C.S.

"A Visit to the Howling Derivishes at Constantinople," by H. N. Draper.

"Interesting Selections from Fifty Cases of Railway Accidents," by Austin Meldon, F.R.C.S.

MEETINGS OF THE SOCIETIES.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—This (Wednesday) evening, at 7.30, Council Meeting, 8 o'clock, Surgeon-General Joseph Kwart, M.D. "Is the Climate of the Indian Hill Sanitaria beneficial in Scrofula, Tuberculosis, and Phthisis?"

HARVEIAN SOCIETY.—Thursday, Jan. 5th, at 8.30 p.m., Mr. Field, "On Cases of Removal of Osseous Tumours from the Auditory Canal."—Mr. Knowsley Thornton, "On Encysted Purulent Peritonitis, with cases."

ROYAL INSTITUTION.—Thursday, Jan. 5th, at 8 p.m., Prof. R. S. Ball, "On the Solar System further considered."

ROYAL INSTITUTION.—Saturday, Jan. 7th, at 3 p.m., Prof. R. S. Ball, "On How we learn facts in Astronomy."

MEDICAL SOCIETY OF LONDON.—Monday, Jan. 9th, at 8.30 p.m., the first Lettsomian Lecture.

ROYAL MEDICAL CHIRURGICAL SOCIETY.—Tuesday, Jan. 10th, at 8.30

CLINICAL SOCIETY OF LONDON.—Friday, Jan. 13th, at 8.30, Annual Meeting: Election of Officers.—Adjourned Discussion on Cases of Myxodema.—Dr. W. H. Keesteven, "On a Case of Unilateral Xanthopsia."—"Cases of Renal Calculus removed by Operation," by Mr. Beck, Mr. Butlin, Dr. Whipham, and Mr. Haward.—Dr. S. Mackenzie will exhibit a case of Lupus-variola.

Vacancies.

City of Dublin Hospital.—House Surgeon. Salary, £100 per annum. For further particulars apply to Surgeon Wheeler. (See Adv.) Gravesend Dispensary and Infirmary.—House Surgeon and Dispenser. Salary, £100, with board. Applications to the Hon. Sec. before Jan. 10.

Huddersfield Infirmary.—Senior and Junior House Surgeons. Salaries, £80 and £40 respectively, with board. Applications to the Hon. Sec. before Jan. 21.

Leamington Amalgamated Friendly Societies Association.—Resident Medical Officer. Salary, £300, with residence. Midwifery fees extra. Applications to the Secretary, 6 Woodbine Street, Leamington.

Lincoln County Hospital.—House Surgeon. Salary, £107, with board. Applications to the Secretary before Jan. 16, of whom also further particulars can be obtained.

Nottingham County Lunatic Asylum.—Assistant Medical Officer. Salary, £100, with board. Applications to the Chairman of Committee at Snettton, Nottinghamshire, by Jan. 5.

Appointments.

CALLAN, M., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer of Termonfeckin Dispensary, co. Dublin.

CHAVASSE, T. F., M.D., C.M., F.R.C.S. Ed., Surgeon to the Birmingham General Hospital.

DICKINSON, T. V., M.B. Lond., L.R.C.P. Lond., Resident Obstetric Assistant to St. George's Hospital.

FERGUSON, D., L.R.C.P., L.R.C.S. Ed., Medical Officer to the Workhouse of the Newtown and Llanidloes Union.

GOWANS, W., L.R.C.P., L.R.C.S. Ed., Surgeon to the Ingham Infirmary, South Shields.

HUDSON, T. J., M.B. Durham, L.R.C.P.L., M.R.C.S., Resident Medical Officer to the Leeds Public Dispensary.

JAMES, C. A., L.R.C.P., M.R.C.S. Ed., Resident Medical Officer to the Stamford Hill and Stoke Newington Dispensary.

MCLAHLAN, S. F., M.B., C.M. Glas., Medical Officer of Health for the Longtown Rural Sanitary District.

MORRIS, E., M.D. St. And., F.R.O.S., Senior Surgeon to the Johnston Hospital, Spalding.

ORPEN, A., L.R.C.S., L.K.Q.C.P.I., Medical Officer for the Second District of the Chipping Norton Union.

ROBERTSON, J. J., M.B., C.M. Glas., Medical Officer for the Montgomery District of the Forde Union.

RYAN, W. H., L.K.Q.C.P.I., Medical Officer for the Hunslope District of the Newport Pagnell Union.

WATERS, A. J. G., L.R.C.P. Ed., M.R.C.S., Medical Officer for the Brandon District of the Thetford Union.

Births.

BURWOOD.—Dec. 30, at Strathmore, Ealing, W., the wife of Dr. Burwood, of a daughter.

Marriages.

SMYLY—TWEEDY.—Dec. 28, at St. George's Church, Dublin, William J. Smyly, M.D., to Eleanor Colpoys, second daughter of Henry Tweedy, M.D., of Rutland Square.

Deaths.

BIRD.—Dec. 17, at Chelmsford, Henry Bird, M.R.C.S., aged 82.

BREACH.—Dec. 23, at Aston Upthorpe, Wallingford, John Breach, M.R.C.S., aged 68.

BROOKES.—Dec. 29, at 276 Kennington Road, London, Ada Jessie, wife of F. W. Brookes, M.R.C.S.

COOPER.—Dec. 25, at the Limes, Slough, Thomas Henry Cooper, M.D., aged 68.

FLOWER.—Dec. 19, at Warminster, Wilts, Thomas Flower, M.R.C.S., aged 86.

GRIFFIN.—Dec. 24, at 11 East Park Terrace, Southampton, R. W. Waudby Griffin, M.D., aged 45.

HARVEY.—Dec. 24, at his residence, 7 Upper Merrion Street, Dublin, Reuben J. Harvey, M.D.

LODGE.—Dec. 24, at Shaw Street, Liverpool, R. T. Lodge, M.D. St. And., M.R.C.S., aged 62.

OLDHAM.—Dec. 26, at Lucastes, Hayward's Heath, James Oldham, F.R.C.S. (late of Brighton), aged 64.

WANTED, a duly REGISTERED SURGEON,
to act as HOUSE SURGEON in the CITY OF DUBLIN HOSPITAL, Salary £100 a year, with apartments, light, fuel, and attendance. For further particulars apply to Surgeon Wheeler, 27 Lower Fitzwilliam Street, or at the Hospital.—Applications must be lodged on or before Tuesday, the 10th January, 1882, addressed to the Secretary of the Medical Board, City of Dublin Hospital, Upper Baggot Street, Dublin.

MENSTRUATION AND ITS DERANGEMENTS.

By ALFRED MEADOWS, M.D., F.R.C.P. &c.,
Physician to, and Lecturer on Midwifery and Diseases of Women
and Children at, St. Mary's Hospital.

Abstract Report of Harveian Lectures for 1881.

(Continued from page 2.)

LECTURE III.—(Concluded).

Stricture of the os uteri, whether of the internal or the external opening, or in cases where both are concerned, admits of being readily diagnosed. Pain due to such conditions will be coincident with the discharge of secretions, and may also be experienced before this takes place; but it is not the accompaniment of the act of ovulation. This pain possesses a distinctive bearing down or forcing character, and whenever circumstances arise to expedite the rapidity with which the discharge finds an outlet, immediate reduction takes place in the extent of the painful sensations.

The cervix in these cases is often conical in form; the uterus hard and elongated, but without hypertrophy; the external os a small, circular, depressed opening, not rarely too minute to admit the introduction of a sound, while the os internum may be excessively minute. The existence of these conditions will enable the most certain conclusions to be drawn respecting the nature of the disease, and thus it may be said that all the forms of dysmenorrhœa admit of accurate diagnosis when due weight is given to the features distinctive of illness in each instance. In pursuing the inquiry, a first point to determine is, always, the seat of the pain complained of—whether, that is, it be ovarian or uterine, as on the answer to this question must depend the method pursued with the object of remedying the existing mischief. Mechanical treatment of painful menstruation will, of course, be demanded in certain cases. What they are will be apparent from the facts already considered, and

the inferences drawn from them. Under any circumstances, however, where a tumour blocks the canal whereby the uterine contents should properly escape, its removal will be absolutely necessary.

According to some authorities, stricture of the cervix *always* occurs at the external os; but the statement cannot be supported, for, as a matter of fact, whenever a single one of the two openings of the cervix uteri is so affected, it is discovered to be the internal far more frequently than the external. As a rule, however, both are found to be implicated, and a proper appreciation of the condition of things thus brought about is essential to ensure successful treatment of these cases by the practitioner. Thus, if the external os be alone divided when a stricture extends beyond it in the cervical canal, no relief to pain will ensue, but the only result produced will be artificial creation of an unnatural cervix by a most unscientific procedure. Legitimate treatment may be pursued with the aid of either knife or bougie, but the latter is less reliable than the former, and its employment is little deserving of recommendation. As a general rule, it is safest to assert that *all* cases of stricture of the cervix should be treated, if fit to be operated on at all, by division of both the external and the internal os uteri. Here, again, it must be particularly borne in mind that, previous to deciding on this proceeding, every assurance must be obtained to the effect that neither ovaries nor uterus are in any way diseased, for as surely as they are will acute inflammatory symptoms supervene after operation. This latter, too, is, of course, contra-indicated in patients who exhibit the strumous or tubercular diathesis; and when it is performed, strict rest in the recumbent position must be rigidly enforced. In doing the operation, let the cuts be made deep and uniform, and their edges subsequently be well separated by an appropriate stem, and kept scrupulously clean and sweet. At the end of a week the stem should be replaced by the glass stem introduced by Dr. Meadows some time ago, and which the patient should continue to wear till after the first "period" has been passed. No accident, said Dr. Meadows, ever occurred from the use of these instruments, which possess the advantages of cleanliness, non-corro-

siveness, and rigidity; they had yielded the most satisfactory results in his hands, and he strongly recommended their employment to the profession. A second week of rest to the patient must be enjoined, and at the end of that time a little gentle exercise may be indulged in, gradually increasing to the usual amount taken.

Flexions.—In the discussions which have from time to time taken place respecting flexions of the uterus, various explanations of the pain accompanying them have been advanced. According to Dr. Graily Hewitt, it is due to mechanical pressure of the organ, while others aver that congestion simply is the cause of it. Dr. Meadows concludes that it is more frequently a consequence of congestion than of flexion, and as tending to prove this, he instanced many cases of flexion treated by himself, in which no pain at all was experienced, and in all, too, congestion was wholly absent. It must be added, however, that all these were observed during periods of non-menstruation, and that when menstruation occurred in them, pain attended the discharge, thus far lending an appearance of support to the mechanical theory. Successful treatment of all cases of this description requires that the cause of obstruction should be removed, and in admitting this, Dr. Meadows said he yielded all the adhesion he was prepared to offer to the mechanical theory. The objections to this latter explanation are found in the vascular arrangements of the uterus, which, as described in Lecture I., is supplied by these arteries, and relieved by venous blood by two distinct paths, so that the upper and lower portions of the viscus are independent in this respect. Hence Dr. Hewitt's analogy between a flexed finger, or banded arm, and strangulated uterus, does not hold, inasmuch as, while in the former there is but one path along which blood is able to return, viz., up past the constriction, in the uterus an entirely different arrangement obtains, and one that renders strangulation a matter of impossibility.

The first indication for treatment, is that supplied by the congested condition of the uterus, which must be immediately relieved, and, this done, be followed by efforts at replacement. Flexions, it is necessary to know, are more difficult to treat successfully than are versions, and anteversions than retroflexions, while to effect any tangible good with them the use of an intra-uterine stem will be called for. The Hodge pessary is not an efficient instrument for the cure of retroflexion; it does no more than offer a support to the womb, the fundus of which remains retroflexed on the top of the pessary *in situ*, a condition easily diagnosed on introducing the sound. A stem alone is competent to afford the relief required, which it secures by passing to, and supporting in a proper position the top of the uterus. The most suitable stem also is the glass instrument already referred to, and it will be found to be quite free from the objections which might appear, at first thought, to weigh against it. Breakage is all but impossible, well protected and surrounded by soft parts, as it must be when fixed *in utero*; indeed, in many hundreds of cases in which it has been used, no accident has ever taken place. Even the stem however, is not a preventive of version of the uterus, and to meet it a Hodge pessary may be worn with advantage also, or an improved form of instrument introduced by Dr. Meadows under the name of "compound spring pessary." Thus means are now available for the certain treatment of retroflexion of the uterus.

Anteflexion is a more difficult condition to treat, and does not easily admit of being cured. It produces most troublesome consequences, through the influence exerted on the bladder by the displaced uterus, and by reason of its necessary association with sterility in those who are subject to it. The only instrument that offers any trustworthy chances for its treatment, is a padded Hodge's pessary, which should be applied in the reverse way to that usually followed in retroflexion. Failing good results from the use of this apparatus, trial should be made of the intra-uterine stem or of the spring pessary

mentioned above. Not infrequently, however, very serious complications accompany the existence of ante-flexions.

Vicarious Menstruation is a subject about which there is but a small amount of reliable information to be obtained, and which is consequently but little understood. Treatment of it has hitherto resulted in producing no benefit, and in all probability nothing in this direction will be obtained, until a careful, and precise scientific investigation of the conditions giving rise to it is carried out. Properly considered, it will be found to present many more characteristics of a normal than of an abnormal process, and the due unravelling of the problem will be a work of perhaps not a far distant future. In this pursuit consideration must be given to the influences exerted, and the functions fulfilled by the ovaries and their servant the uterus, and also to the parts played by the vascular plexuses so freely distributed in the regions of these central organs. Neither must it be forgotten that the stimulation which brings about arterial changes to which, in chief, the flow of fluid corresponding to a menstrual period is due, occurs as well in whatever situation the discharge may make its appearance, because the truth may not improbably be found in intimate dependence on those physiological processes with which we are already well acquainted. Vicarious menstruation, it should be mentioned, is more frequent from some part of the alimentary canal than in any other situation; or from the kidney. In relation to this fact it is significant to remember that the ovaries are in intimate nervous connection with these organs, as demonstrated in the previous lectures. Renal menstruation, therefore, is hardly more a misnomer than hysterical urine, and the suggestion contained in the comparison may not improbably be a fruitful one in the future.

CLINICAL LECTURES ON SYMPTOMS.

Delivered in the Wards of the Hospital.

By FREDERICK T. ROBERTS, M.D., B.Sc., F.R.C.P.,
Professor of Materia Medica and Therapeutics at University
College; Physician and Professor of Clinical Medicine at
University College Hospital, &c.

LECTURE III.—ON GENERAL SYMPTOMS AND CONDITIONS. (Continued.)

We were engaged in the last lecture in discussing the general symptoms which you have to recognise, and we now proceed to consider the groups which still remain to be noticed.

III. SYMPTOMS DUE TO EVIDENT BLOOD-STATES.—There are certain conditions of the blood which give rise to obvious phenomena, affecting more or less the entire system, and often of a striking character. These are:—

1. *Anæmia.*—The appearances characteristic of various degrees of anæmia are of very common occurrence, and are easily recognised, being evident in the colour of the face and visible mucous membranes. It is, therefore, a condition for which you must always be on the look-out, and of which you should take special notice. There may be some peculiar tint of the skin accompanying the anæmic pallor, as in chlorosis and chronic lead-poisoning. A certain degree of dropsy may also be directly due to anæmia.

2. *Plethora.*—The aspect induced by a plethoric state of the blood and circulation is, in some instances, very marked, and needs also to be recognised.

IV. SYMPTOMS ASSOCIATED WITH PARTICULAR ORGANS.—The symptoms which may be placed in this category, as affecting more or less the entire body, but still having a definite local origin are the following:—

1. Extensive subcutaneous dropsy, dependent usually upon cardiac or renal disease.
2. Jaundice, associated with the hepatic organs.
3. Signs of imperfect blood-aëration, and of over-loading or stagnation of the general venous system. As affecting the whole body, the appearances indicative of this condition owe their origin to the respiratory organs or heart. They

may be strikingly evident, however, in the face, neck, and upper part of the body, when due to some local obstruction of the superior vena cava. They may be acute or chronic, the former culminating in the signs of *asphyxia* or *apnœa*; the latter in those characteristic of the condition termed *cyanosis*. Not only is the colour of the skin and mucous surfaces altered, but this is often accompanied with a bloated appearance of the face and neck, visible enlargement of the small vessels, and dropsy.

4. The different forms of unconsciousness. Loss of consciousness is, of course, immediately due to some cerebral condition, but it is necessary to recognise certain main general varieties, so far as organs are concerned, according to the part where such condition has its origin, and they are:—(1.) *Cerebral*, where the original cause is in the brain itself, constituting *coma*. (2.) *Respiratory*, where the unconsciousness is due to *asphyxia*. (3.) *Cardiac*, the condition being one of *syncope* or *fainting*. (4.) *Urinary*, the insensibility resulting from *uræmia*. It must be remembered that unconsciousness may depend upon the introduction of poisons from without; the development of morbid products within the body; the state of shock or collapse; and other causes; but the condition can then be traced directly to implication of one or more of the organs mentioned.

5. Certain nervous symptoms, such as general restlessness or twitchings, choreic movements, or general paralysis.

V. SPECIAL SYMPTOMS.—In this division I would place:—

1. Temperature.
2. The pulse.
3. The tongue.

You are doubtless aware that it is a routine practice in our wards to take the temperature of the patients by means of the clinical thermometer, at more or less frequent intervals according to the nature of the case. I would urge you strongly always to bear in mind the great value of this simple instrument in ordinary practice, and not to neglect its use whenever it appears likely to give you any assistance in diagnosis. Although abnormal bodily temperature is thus determined really by "physical examination," yet it may be conveniently regarded as, and is to all intents and purposes, a general symptom. As to the pulse and tongue, they may be placed in the same category, because, although in themselves local, they give much valuable information as to general conditions, and are almost universally examined by practitioners as a matter of routine, without any reference to diseases of the systems to which they severally belong. Indeed, the danger is lest "feeling the pulse," and "looking at the tongue," become mere formal acts, without any clear appreciation of the objects for which they are performed; while other points, which deserve attention or recognition, are neglected or overlooked.

In dealing with the remaining groups, it will suffice for the present to explain what each is intended to include, and merely to enumerate the individual conditions or diseases which belong to the several divisions.

VI. SIGNS OF PATHOLOGICAL CONDITIONS.—This group scarcely needs any explanation, and it will be enough to state that you ought to be quite familiar with the combinations of phenomena characteristic of the following general pathological states:—

1. Fever or pyrexia.
2. The "typhoid state."
3. Collapse and shock.
4. Septicæmia and pyæmia.

VII. TEMPERAMENTS.—A temperament may be defined as the sum total of the anatomical and physiological peculiarities of an individual. Four main temperaments are recognised, namely:—(1) *Sanguine*. (2) *Lymphatic*. (3) *Bilious*. (4) *Nervous*. Some authorities attach undue importance to these temperaments, and certainly many individuals are met with who hardly fall under either of them. At the same time you should learn what are the signs of each, so as to be prepared to take note of a temperament, when it is obvious and marked, especially in its relation to the occurrence of particular complaints.

VIII. DIATHESSES AND CACHEXIE.—By many these terms are regarded as synonymous, but others make a distinction between them. Thus a *diathesis* is made to signify a morbid condition of the system, or a constitutional state, usually hereditarily transmitted, of a particular or specific nature, and liable to lead to the development of local lesions, peculiar to and characteristic of such condition. A *cachexia* is the general state of the body actually produced by the

effects of one of these morbid conditions, whether it be hereditary or acquired. For our present purpose it will be sufficient to state that each of these diatheses or cachexiæ is supposed to be characterised by certain more or less obvious signs, which, taken as a whole, reveal its existence in an individual. With regard to some of them this is unquestionably true, and you ought to be able to recognise them without much difficulty; but, in the case of others, the signs are by no means so definite and reliable, while they are often absent, although the diathesis exists. The following is a list of the acknowledged diatheses and cachexiæ, and with which you should be familiar:—

1. Cancerous or malignant.
2. Scrofulous or strumous.
3. Tuberculous.
4. Ricketty.
5. Gouty.
6. Rheumatic.
7. Malarial.
8. Alcoholic.
9. Syphilitic, especially congenital.

IX. SPECIAL DISEASES.—It is a fact that there are not a few cases in which the general aspect of a patient, or certain combinations of general symptoms, at once reveal that he is suffering from disease of some particular organ, or even from a particular disease. In the case of some organs, indeed, such as the spleen, it is by the general condition that attention is often first attracted to them. But while making this statement, and before enumerating the diseases which may be thus recognised, I would most emphatically warn you against placing too much reliance on this method of diagnosing them. Physicians in former times are credited with remarkable skill and acumen in the diagnosis of cases in this way. This may be true, or it may not, for the means of verifying a diagnosis were not so available then as they are now, but, at any rate, this faculty does not belong to the majority of us at the present day. Of course it is quite easy to recognise some diseases at a glance, and a proportion of cases of certain other affections, when the general signs are sufficiently marked, but the fact remains that in many instances these signs do not exist, or they are not developed until the mischief is far advanced. I feel sure that a great deal of harm is being done by students being taught, or getting the notion for themselves, that they may place reliance on the appearance of patients for the diagnosis of various diseases. The result is that many cases of serious complaints are not recognised until too late for treatment, or, perhaps, not at all. Therefore, I warn you most strongly against this danger, and while acquiring full knowledge of the general signs which reveal to you particular diseases, remember that these are often absent, and to expect and wait for them in every case is one of the gravest errors you can commit. I will now enumerate the most important conditions belonging to this group.

1. Certain pulmonary diseases, especially acute pneumonia, phthisis, emphysema, and bronchial asthma.
2. Some cardiac diseases.
3. Certain acute fevers and allied affections (apart from any eruption, which, of course, you should know in each case), especially typhus fever, erysipelas, rheumatic fever, mumps ague, cholera, yellow fever.
4. Acute, and some forms of chronic Bright's disease.
5. Acute peritonitis.
6. Addison's disease.
7. Hodgkin's disease.
8. Leucocythæmia.
9. Diabetes.
10. Scurvy and purpura.
11. Lead and some other forms of metallic poisoning.
12. Certain nervous conditions or diseases, such as mania, idiocy, delirium tremens, hysteria, epilepsy, chorea, paralysis agitans, general paralysis of the insane, advanced wasting paralysis, pseudo-hypertrophic muscular paralysis, &c.
13. Goitre and exophthalmic goitre.
14. Many cutaneous diseases.

A little consideration of the list which I have just given you, will enable you to fix upon illustrations in support of the warning which I previously urged upon you. Perhaps some of you think that it is an easy matter to recognise consumption in a patient, but there are large numbers of individuals suffering from this disease, whose general appearance and condition give no hint whatever of its existence, and we have had cases in these wards during the present session illustrating this important truth.

CARBOLIC ACID: ITS LOCAL AND INTERNAL USES AND ITS POISONOUS EFFECTS (a)

By FREDK. W. WARREN, M.B., F.R.C.S.,

Demonstrator of Anatomy, Royal College of Surgeons, Ireland.

In laying before the Society the results of observations and experiments made by myself, extending over a period of six years, upon the internal and local uses of carbolic acid and its toxic effects, I wish to exclude from my paper the surgical application of the acid as an antiseptic in the treatment of wounds. I adopt this course because, firstly, I think it is now unquestionably settled by modern surgeons that the antiseptic method of dressing wounds has achieved great triumph, and has certainly been a forward stride towards truth; and secondly, because this aspect of the subject has been already twice ably and exhaustively debated in this Society during past sessions. It is my object to bring under the notice of the Society some cases in which I found carbolic acid most successful as a therapeutical remedy, and in which the drug is not very widely used, with the hope of eliciting the opinion of the members upon this remedial agent.

The first class of cases in which I have found carbolic acid a most powerful therapeutical agent is typhoid fever. I have now employed it in about twenty cases with two deaths. It is most applicable to those cases of the fever where death is threatened from the "putrid state" of the old writers, when in the course of the second week there is nocturnal delirium, copious diarrhoea, depression, stupor, with sordes on the teeth and gums, and dry brown tongue, muscular tremors, and bronchial catarrh. I have found the acid most useful. It must be employed in large doses, freely diluted (ʒss.—ʒj. daily in ordinary drink or abundance of water). It evidently acts as an antiseptic, and also as a nervine tonic, accelerating the healing and cicatrization of the intestinal ulcers. Small doses, perhaps, in consequence of the nervous stupor which prevails in enteric fever are of little or no therapeutic value.

I shall merely read a few brief notes of two or three cases which will serve to elucidate the above remarks.

CASE I.—The patient was a delicate girl, æt. 14. The ordinary symptoms of the disease had been present for ten days, when, towards the close of the second week, there appeared a good deal of nocturnal delirium, profuse diarrhoea, an evening temperature of 105°, pulse very rapid, dicrotous and weak, great nervous prostration, sordes on the nostrils and teeth, hæmorrhagic discharge from the gums, fauces, and tongue. I now determined to try carbolic acid in solution, and ordered the following mixture: Acid carbol., ʒss.; glycerine, ʒj.; and water ½ a pint. An ounce to be taken every three hours. The next day the patient was much better; the evening temperature only rose to 104°, and two weeks later the patient was convalescent.

CASE II.—A young adult, of 22 years, was the subject of very severe enteric fever; developed towards the commencement of the third week those low symptoms known as the typhoid state, low muttering delirium, cephalalgia, dicrotous pulse, intestinal hæmorrhage, &c. I at once placed the patient upon the solution of carbolic acid used in the first case; he took it with avidity, and in a few hours the ½ drachm of the acid had been consumed. From this time the patient began to mend. The remedy was continued for a few days with the most beneficial results and speedy convalescence.

I will not burden the Society with any further cases, but merely allude to some of the opinions of other writers upon this subject.

Mr. Henry Weeks, in the *Lancet*, of Feb. 1880, p. 951, speaks very enthusiastically of the use of carbolic acid internally in the treatment of a well-marked case of typhoid fever, and thinks it justifies a reconsideration of Dr. Jenner's well-known dictum that it is not possible to

cut short typhoid fever. Six minims of carbolic acid glycerine were administered every four hours. In forty-eight hours the temperature fell from 105.5° Fah. to 99° Fah. M. Chapell, in *L'Union Médicale*, No. 103, asserts that tar-water freely imbibed, and also used as a lavement, is able to cut short the typhoid state in two or three days, and to cure true typhoid fever in eight or ten days. In the *Lancet*, 1869, p. 471, is a statement, on the authority of M. Pécholier, of Montpellier, that in sixty cases the vast value of creasote, both internally and in enemata, was most marked. Mr. F. Hunt, in the *Lancet*, May, 1880, p. 751, records his experience, which, although it does not confirm the assertion made by Mr. Weeks, still enables him to recommend its further use, giving it in larger doses than two or three grains every four hours.

I have made a good many observations upon the anti-catarrhal properties of carbolic acid and found it most useful. In the early stage of catarrh, when the symptoms first develop themselves, such as a disagreeable prickling sensation in the throat, suffusion of the eyes, sneezing, &c., the spray of a 2 per cent. solution of the acid inhaled every half hour is sufficient to cut short and abort the attack. Clothes hung over the head of the bed, saturated with carbolic acid solution of 20 per cent., materially relieve subacute catarrhs of the larynx and pharynx, and quiet troublesome nocturnal cough. In asthma, following an acute or chronic catarrh of the bronchi, this treatment is most surprising in its results. This treatment is not applicable to acute cases where the parts are very red, the secretion profuse, the cough violent, as in phthisis.

Perhaps if there is one disease more than another in which the acid is useful by this method of inhalation, it is whooping-cough. I now in every case use the atomiser, disseminating the spray of a 20 per cent. solution about the room several times through the day, and hanging flannel cloths dipped in the solution over the head of the bed at night. In my hands this treatment invariably cuts short the catarrhal stage of the disease, and abates the paroxysms of the spasmodic stage. It has the great advantage of being easily used, even with the very youngest children.

Mr. Blake first drew attention to this treatment of pertussis in 1868 in the *Medical Times and Gazette*, and he gives a diagram of a useful inhaler.

Birch-Hirschfeld recommends not only temporary inhalations of carbolic acid in whooping-cough, but directs his patient to stay permanently in an otherwise well-ventilated room, in which frequently a 20 per cent. solution of carbolic acid has been dispensed by means of a spray-producer.

Dr. Thorner recommends inhalations of the acid from the commencement of the convulsive period. It is advisable, he says, to begin with a 1 per cent. solution, and quickly to increase the strength to 2 per cent. The urine, he says, must be carefully watched, and the inhalations discontinued as soon as the beginning of intoxication is manifested. In cases of young children, or of great irritation of the air-passages, the children ought to be brought three times daily into a small room in which a carbolic acid spray of the prescribed strength is working. I have never known any bad results to occur in my own cases.

Leenan (*St. Petersburg Medicin Wochenschr.*, 1879) strongly recommends the use of carbolic acid inhalations in whooping-cough, and in order that it may have the best effect, he advises that it should be administered during sleep, as it is difficult to ensure that a child should inhale sufficiently long, or enough, of the medicament while awake. Woollen material saturated with a 5 per cent. solution should be hung about the bed.

Carbolic acid vapour probably acts by exerting an anæsthetic influence upon the hyperæsthetic mucous membrane of the air-passages.

A strong plea for the value of carbolic acid in malarial diseases is published from the pen of Dr. A. G. Tebault. He says: As a prophylactic, carbolic acid given in 1 grain doses, at intervals of three to six hours, has in my hands yielded comparatively very happy results, even in cases

(a) Read before the Surgical Society of Ireland. Discussion will be found on page 27.

where unmistakable prodroma of malarial fever were actually present. In experiments, extending over seven years on my own person and others, feelings of lassitude, malaise, cutaneous tremors, disturbed sleep, furred tongue, nauseous taste, and anorexia often gave way under this treatment within twenty-four hours; and a pulse, hitherto jerking and irritable, became calm and of the natural rhythm, while a soothing pleasant sensation pervaded the system. No fever manifested itself in any of the cases, on the contrary, the person felt refreshed and buoyant. No other agent which I have employed has ever superseded carbolic acid as an apparent disinfectant of the system, and this after anxious thought for years, is, to my mind, the first glimmer of light that may lead to the discovery of means to act directly on the poison of fever."

Led by these observations of Dr. Tebault, I tried the acid in the doses recommended in three cases of intermittent fever occurring in the employees of St. James's Gate Brewery, who had served in tropical climates, with very gratifying results. I also administered the drug in three cases of hæmorrhagic small-pox, but without any avail. However, three out of six cases of purpuric small-pox recovered on this treatment—the purpuric patches in the groins and axilla rapidly disappearing.

I have now used carbolic acid as an injection into painful and inflamed hæmorrhoids, in six cases, with success in every case. As recommended by Dr. Pooley, in the *Toledo Medical and Surgical Journal*, November, 1877, I injected with an ordinary hypodermic syringe, deep into the substance of the pile, three or six drops of crystallised carbolic acid, liquefied by heat. Each hæmorrhoid was injected in succession. The pain was slight and soon ceased. The carbolic acid caused a slough which soon separated, and the cure was accomplished in a week or ten days. The cases to which this treatment applies are those of inflamed or irritable hæmorrhoids, either external or partly contained within the rectum. This treatment is contra-indicated for internal bleeding piles and for those wholly external that are flabby and comparatively harmless.

Prof. Andrews lays down the following rules for the treatment of piles by injection of carbolic acid:—

1. Inject only internal piles.
2. Use dilute form of the remedy at first, and stronger ones only when these fail.
3. Treat one pile at a time, and allow from four to ten days between the operations.
4. Inject from one to six drops, having smeared the membranes with cosmoline to guard against dripping; inject very slowly, and keep the pipe in place a few moments to allow the fluid to become fixed in the tissues.
5. Confine the patient to bed the first day, and also subsequently, if any severe symptoms appear. Prohibit any but moderate exercise during the treatment.

Dr. J. E. Brackett, Professor of Materia Medica and Therapeutics in the Howard University, writes in the *Therapeutic Gazette*, of March, 1880, that during the past year he has had frequent occasions, both in private and hospital practice, to thoroughly test Prof. Hüter's method of treating erysipelas by hypodermic injections of carbolic acid, and with the most satisfactory results—

R Carbol. acid;
Alcohol, āā ʒss.;
Aq̄æ, ad ʒij. ℥

Five syringefuls to be injected where redness was most intense, and above its upper margin. To be repeated if necessary.

Dr. Brackett thinks this treatment of erysipelas vastly superior to any other yet attempted or introduced. I have never tried this treatment myself.

Drs. Taube, of Leipzig, and Edcl recommend the submucous injection into the tonsils twice or thrice daily of about half a syringeful of about 3 per cent. solution of the acid, with ice-bags to neck, and teaspoonful doses of port or madeira hourly, and turpentine inhalations in croup and diphtheria. I have no personal experience of this treatment.

Dr. Paul Boydt has observed in the service of M. Verneuil the happy effects obtained by the surgeon in treating extensive burns with carbolic acid. From the cases which he has himself seen, and from three which Busch, of Rome, has made known, Dr. Boydt has arrived at the following conclusions:—

1. This plan of treatment moderates the inflammation which accompanies the elimination of the sloughs.
2. Certain formidable complications, such as acute septicæmia, purulent infection, &c., are prevented.
3. The suppuration is diminished.
4. As concluded by Dr. Busch, those parts only are eliminated which have been destroyed by the heat, and the cicatrix is admirably smooth and extensible.

I have never, for some years, employed any other treatment in extensive burns, and I see a very large number of such cases in St. James's Gate Brewery.

The number of fatal cases of carbolic acid poisoning now on record is quite large, and the list is certainly growing. The symptoms, though varying slightly, are, upon the whole, pretty uniform. They almost always appear rapidly after the injection of the poison. Dr. Taylor (*Philadelphia Medical Times*, vol. II., pp. 284) records a case in which about an ounce caused insensibility within ten seconds after taking the fatal draught, two minutes afterwards the patient was pulseless, with irregular distant gasping respirations, and in less than a minute later was dead, apparently from cardiac paralysis. Generally some minutes elapse before the symptoms develop themselves; nausea, cold sweats, stupor deepening rapidly into insensibility, or collapse, are the most frequent phenomena.

The following are the notes of a case which came under my own observation:—

Michael H., æt. 40, a fireman in a distillery, of strong and muscular form, was admitted into Steeven's Hospital, Nov. 26, 1874, with the following symptoms:—Pallor of the face, coldness of the surface, perfect insensibility and coma, respirations slow and laboured, the pupils being fixed and insensible to light, and the pulse feeble, and almost imperceptible at the wrist. There was no erosion or mark upon the mucous membrane of the lips or mouth. The history given by his fellow workmen was as follows:—That while engaged at his work he suddenly fell to the ground, as they described it, in a "fit;" they also stated that he drank but one glass of whisky an hour previously to his losing consciousness. On applying my nose to the patient's mouth I distinctly perceived an odour resembling that of carbolic acid or creasote, to which I drew the attention of the class. My suspicions were confirmed very shortly afterwards by the foreman of the distillery sending me a small bottle of dark-coloured fluid, of which he stated the patient had partaken in mistake for whisky. This fluid had the characteristic smell of carbolic acid, was of a dark brown colour, and was evidently the impure commercial form of the acid, which is used for disinfecting purposes.

As the patient presented all the symptoms of extreme vital depression, I first administered a turpentine enema, and applied sinapisms to the calves of the legs. I then introduced the stomach-pump, and evacuated a considerable quantity of dark fluid, corresponding in its physical characters to the contents of the bottle sent me by the foreman of the distillery. I continued to wash out the stomach with tepid water until it returned clear as when introduced. I then pumped into the stomach a few ounces of a saccharated solution of lime, which is undoubtedly the best antidote. The patient still remaining unconscious, I administered a couple of ounces of brandy by the rectum. He now showed some symptoms of returning consciousness. Ordered ammonia to be applied to the nostrils occasionally through the night. The pulse was now greatly improved in strength.

The next morning the patient was perfectly conscious, and complained of great pain over the epigastrium and in the track of the œsophagus. Vomited everything he

took. There was considerable irritation of the lips. Had a perfect recollection of one of his comrades handing him a stone jar, and desiring him to take a drink, which he did, thinking it was whiskey; stated that the liquid had a very pungent, burning taste; after this he remembered no more. He now passed about 8 oz. of very dark olive green, almost black, urine, though perfectly clear, and somewhat translucent when held towards the light. Sp. gr. 1.025, intensely acid reaction. No albumen or any trace of blood could be detected after most careful examination. Ordered five minims of liq. opii sed. every two hours; to have thin arrowroot and milk, with lime-water in small quantities at a time, and a linseed-meal poultice to be applied constantly over the epigastrium. From this time onwards the patient improved rapidly. The urine became daily paler in colour, depositing as it did so a copious cloud of urates. The analysis of the urine was conducted by Professor Bell, of London, who failed to detect albumen, blood, or the acid itself. In the cases recorded by J. A. Waldenström and Aug. Almen, of Upsala, in the second and third numbers of the "Transactions" of the Medical Society of Upsala, in which changes were produced in the urine by the external application of the acid, it presented the usual dark green characteristic appearance, with albumen in small quantities, and no blood; but the presence of carbolic acid was indubitably and unmistakably demonstrated. Waldenström believes that the change of colour in the urine occurs *only* under the external application of the acid, and he records a case in which the external use of carbolic acid merely produced a transitory albuminous condition of the urine. That the internal use of the acid *will* produce the discolouration of the urine was indisputably proved in the above case. The colour is probably due to the colouring matter in the blood escaping in the shape of an increased amount of indican. The symptoms of carbolic acid poisoning are most intense when the acid is subcutaneously introduced, and next when absorbed by the mucous membrane of the stomach or rectum. A dilute solution is more readily absorbed than the concentrated acid, owing to the caustic, coagulating action of the latter, which rather retards absorption. The acid, when absorbed, undergoes various hitherto unknown changes, and is then rapidly eliminated by the kidneys, imparting to the urine a characteristic dark green colour. Only a small portion is eliminated unaltered, and traces of it, with the characteristic odour, may be detected in the blood. Death is caused by asphyxia in consequence of irritation and paralysis of the vagus and of the respiratory centre in the medulla oblongata; sometimes, in large doses, it results from paralysis of the heart, or syncope.

The treatment is far from satisfactory. Wood, in his admirable work upon therapeutics says there is no known substance which can be thoroughly relied on as an antidote. The recent experiments of Husemann, however, indicate that the alkalis have some power in controlling the lethal action, provided they are exhibited in solution, and in great excess. Lime is probably the best of them, given in the form of the saccharate. Husemann's experiments prove that the oils are of very little, if any, use. The stomach should be rapidly evacuated with the stomach pump, and then thoroughly washed out with tepid water.

Dr. Seuffleben recommends sulphuric acid as a remedy for the toxic symptoms produced by carbolic acid. The poisoning is produced by the presence of phenol in the blood, and he says that sulphuric acid combining with this produces sulphocarbolic acid which is innocuous. He has treated several cases successfully on this principle. The mixture he uses is, dilute sulphuric acid *one part*; gum water *200 parts*; syrup *30 parts*. One tablespoonful to be taken every hour.

I cannot leave this aspect of my subject, viz., the toxicological effects of the drug, without alluding to the toxic properties of carbolic acid in surgical use. I once saw the local application of the acid to the back of an adult cause

death in twenty minutes, preceded by deep coma, widely dilated and fixed pupils, twitching of the muscles, and convulsions. The necropsy revealed profound renal congestion, and cerebral effusion.

At the Seventh Congress of the Society of German Surgeons, held in Berlin in April, 1878, under the presidency of Professor von Langenbeck, Dr. Küster (Berlin) had, in the course of four years' experience of the antiseptic treatment, met with five cases of poisoning by carbolic acid, four of which were fatal. In his first case, stricture of the rectum in a woman, *æt.* 23, the parts were repeatedly washed out with a 2 per cent. solution of carbolic acid; this was twice followed by collapse, and death after temporary resuscitation by artificial respiration. In the second case, the washing out of an empyematus cavity in a child, with a $2\frac{1}{2}$ per cent. solution, was followed by collapse, and death in three hours. The third case, a woman, *æt.* 39, had pelvic periostitis and discharge of pus through the bladder. Incision and washing out the cavity with a solution of carbolic acid was followed by collapse and a fall of temperature to 95° Fahr.; a second irrigation the next day was followed by sudden death. The fourth case was one of resection of the hip in a child, *æt.* 4 $\frac{1}{2}$, who died unexpectedly the next day. The fifth death occurred in a woman, *æt.* 33, who, in consequence of erysipelas following an injury of the leg, had a large abscess under the right gluteus muscle, and suppuration of one knee. Death took place four hours after the suppurating cavities had been opened and injected with a solution of carbolic acid. Dr. Küster is inclined to refer the so-called aseptic fever of Volkmann partly to the action of carbolic acid, and also suspects the existence of a carbolic acid marasmus, leading to death. In anæmic subjects, exhausted by loss of blood, the poison acts more intensely, in consequence of being more readily absorbed. Dr. Küster recommends the greatest caution in the use of the acid. In all possible cases he substituted for it chloride of zinc. Dr. Olshausen records a case of a parturient woman, with rupture of the cervix uteri, in which the parts were *once* washed with a strong solution of carbolic acid, followed by carbolism, with loss of consciousness, mydriasis, twitching of the muscles, but with normal action of the heart and respiratory organs; the symptoms apparently disappeared after three hours. Death, however, soon followed, in consequence, as the autopsy showed, of the passage of carbolic acid into the peritoneal cavity. Professor von Langenbeck recommended at the same Congress, great care in the use of carbolic acid. In some persons, the existence of idiosyncrasy was beyond doubt. He had met with two fatal cases in children in hospital practice.

Dr. Agostini (*Gazetta degli Ospitali*, Feb., 1880) records a most interesting case of suppurative peri-nephritis, in which, having made an incision exposing the renal tissues in the sacro-lumbar region, and inserting a drainage tube, he washed out the wound freely through the tube with a 1 per cent. solution of the acid. The incision was further filled with lint steeped in a 2 per cent. solution, and the whole covered with wadding moistened with a similar solution. Owing to the discharge being very copious, the dressings were renewed daily, and the washing out of the parts very thoroughly performed. In spite, however, of the fact that the local appearances were most satisfactory, the patient's general condition did not continue to improve as it had done for the first ten days after the operation. Periodic attacks of fever occurred daily with a temperature of 102.5 Fahr.; and were followed by a violent attack of dyspepsia upon one occasion with expectoration of a litre of serous fluid, and great prostration. The urine on one occasion was of a dark olive tint. The general condition of the patient becoming steadily worse, and the temperature being always higher after dressing the wound, it was determined to substitute salicylic acid for carbolic acid. The effect of the change was remarkable. Within a few hours the temperature fell to 97.5° Fahr., and continued unchanged till convalescence, which took

place rapidly. The urine showed, only in a very slight degree, the suspicious dark colour of carbohc urine, but there was a remarkable deficiency of the sulphates. The absence or marked diminution of the sulphates in the urine is the most reliable symptom of carbohc acid poisoning, which will, as a rule, be more likely to occur in those exhausted by chronic affections.

Beyond all doubt, from the above and many other recorded cases, carbohc acid exerts a toxic influence at times when used antiseptically. These poisonous effects, as pointed out by Forbes Litton (*London Medical Record*), manifest themselves in two different forms. It may be sudden, the patient sinking rapidly after the application of the dressings, or the symptoms may supervene insidiously, and this is the more common form, possessing greater interest for the surgeon. In the second class of cases the symptoms show themselves only after a certain interval of time has elapsed. A patient after operation will perhaps steadily improve for some days or weeks. He will then become restless, his temperature will rise three or four degrees above normal, symptoms, apparently of incipient septicæmia, will develop themselves, and will, in all probability, be met by a more vigorous employment of antiseptic methods. The condition of the patient, however, becomes daily worse. Nausea, loss of appetite, giddiness, clonic spasms, great prostration, with coma, and even death may close, and, indeed, has already too often closed the scene. In many of these cases there is no room for doubt as to the cause. It has been shown many times that where recovery has taken place, the improvement in the symptoms has coincided in the most marked manner with the cessation of the use of the carbolised dressings. On the other hand, it has been noticed that the symptoms have always become aggravated shortly after the dressings have been applied. The temperature has risen, and the patient has become more restless and uncomfortable, just at the very time when an opposite result might have been looked for.

The most reliable symptom of carbohc acid poisoning, and one which is present in the vast majority of cases, is found in the condition of the urine. According to Baumann (Pflüger's Archiv, Band, xiii.), we have, in the reactions of this fluid, a certain means of diagnosing, not merely the fact, but the actual degree in which the intoxication is present.

Passing over the discolouration and peculiar odour of the urine, the chemical tests are much more important and reliable than the physical appearances, which indeed may be at times absent. Sonnenburgh's test is by far the most reliable. It depends upon the estimation of the normal amount of sulphates present in any given specimen. The sample of urine to be examined is first acidulated with strong acetic acid, and baric chloride added in excess. A copious precipitate, consisting mainly of baric sulphate, is at once formed if the urine be healthy. If acute, or in an advanced stage, scarcely any precipitate will be deposited, the normal sulphates having undergone decomposition and become soluble sulpho-carbolates.

As regards the treatment of carbohc acid poisoning by absorption, the first and most obvious step is to at once cease the use of the acid. Sodhc sulphate forms with carbohc acid within the body soluble and innocuous sulpho-carbolates. Hence, Glauber's salts or other soluble sulphate would appear to be the direct chemical antidote to carbohc acid present by absorption, or otherwise in the blood or tissues.

In the present state of knowledge on the subject, little more can be recommended than increased care in the use of what is undoubtedly a valuable and active medicament. It need scarcely be remarked that the chief danger of absorption exists in the case of large cavities, such as those remaining after the evacuation of ulcers, or where disinfectants have been injected into the larger joints, the pleura or the uterus. It is probable that strong solutions are less dangerous than weak ones, for by coagulating at once the albumen of the tissues they render further absorption impossible. Children and feeble persons are

more susceptible of the tonic effects of the acid than those of a robust type. The main point is to watch every case carefully, and on the slightest sign of any rise in temperature, or any increased restlessness and discomfort after the applications of the dressings, to have recourse to the barium test. It should be borne in mind that the mere quantity of the acid used affords no criterion as to its favourable effects. These will vary in each case with the age, the state of health, and the idiosyncrasy of each individual.

In conclusion, I have only to add that in drawing the attention of the Society to the dangers of carbohc acid, my object has been to elicit the opinions of the members, with a view to grapple with these dangers; for it is by recognising these (happily in this country) extremely rare effects of the acid, and endeavouring to ameliorate them, that we shall contribute to the perpetuation of the greatest boon which has been conferred in the present century on suffering humanity, thanks to the master mind of Joseph Lister.

Clinical Records.

SELECTIONS FROM FIFTY CASES OF RAILWAY ACCIDENTS.

By AUSTIN MELDON, F.R.C.S.I., M.K. and Q.C.P.I.,
M.R.I.A.,

Surgeon to Jervis Street Hospital, &c.

SOME years ago, severe injuries resulting from railway collisions were extremely rare in Ireland; most of our experience in such cases being derived from stray patients who, injured on the other side of the Channel, found their way here before developing the more serious symptoms. Of late years, however, the Irish railways have been, in proportion, as unfortunate as those of Great Britain. There are at present few hospital medical men in Dublin who have not treated cases of permanent injury to the spine, the result of railway accidents. Typical cases of the so-called railway spine are, comparatively speaking, common, but I have selected the following cases, as they appear to me so unusual as to be worth bringing under the notice of my professional brethren.

CASE I.—Michael Hickey, a strong and healthy man, about thirty years of age, whose previous history showed that he had never suffered from any more serious affection than an eruption of boils, was travelling from Kingstown to Dublin on Sunday, the 27th February, 1878, when he met with serious injuries, from the results of which he has since succumbed. The train in which he was seated was stopping at Blackrock station when the mail train approached. The engine man of the stationary train seeing the danger and wishing to lessen the shock, put on full steam, and jerked his train forward with such force as to break the iron couplings connecting the carriage in which Hickey sat with the adjoining one. Immediately after, the mail train came into collision. The patient recollected two distinct shocks, after which he could not remember anything until he found himself at another station, which he then believed to be the next to that at which the accident occurred. It subsequently, however, transpired that this was Sydney Parade, and that the train had previously stopped at Booterstown.

The natural inference is that at most he was in a semi-conscious state until he alighted at Sydney Parade.

A short time afterwards he was found leaning against a wall about one hundred yards from the station, with the contents of his stomach beside him. He was conveyed home, and during the journey he seemed stupid and talked incoherently. During the remainder of the day he was dull and heavy. That night he slept little, starting every few minutes, and on the following morning he was found with complete paraplegia. Dr. Colgan, of Kingstown, was called in, and attended until Thursday, the 21st February.

On Friday, the 22nd February, I saw him in consultation. I found him completely paralysed in the lower extremities, both in regard to sensation and motion. There was incontinence of urine, and he had no control over the sphincters. The temperature was 102, the pulse 110, and

the electric irritability of both legs was lost. He complained of much pain in the back. I applied Corrigan's button at either side of spine. He suffered intensely from the application in the upper dorsal region, but in the lumbar it was not felt. The tongue was but slightly coated. He complained of being unable to concentrate his thoughts, and of having frightful visions when he closed his eyes. He also complained of loss of memory, and headache, and the feeling of a tight cord round his waist.

From the history, and these symptoms, I had little doubt that the case was one of spinal concussion followed by effusion and subsequent myelitis. Perchloride of mercury, together with cupping and blistering along the spine, was the treatment ordered, and after a little time bromide of potash was of service in removing the head symptoms, and later, iodide of potash was prescribed.

On the 4th March I saw him in consultation with the railway company's medical officer, Dr. Forrest. On the same evening he had severe rigors, and the pulse, which had been decreasing, rose to 130. The temperature also rose to 104°. These symptoms commenced to subside twenty-four hours later, and he continued to improve in health.

Some months later he visited me, and I found that he had almost completely recovered, though he was not as strong as before the accident, and could not undergo any great fatigue. I did not again see him until November, 1880, when I was hastily summoned one morning to meet Dr. Boyd, of Kingstown, who had been attending him for some days. I found him comatose with complete suppression of urine.

He died on the same day. No post-mortem was allowed.

CASE II.—On March 1, 1878, I was asked to see Miss H., who had met with an accident while travelling from Dublin to Dalkey on February 27. It appears that the train in which she travelled was proceeding rather slowly towards Dalkey when it came into forcible collision with some loose carriages which were running down the line in an opposite direction. She was rather confused immediately after the accident, and having been assisted out of the carriage, she remained sitting on the embankment for some time without noticing the fact that it was raining. After a short time she walked a distance of about half a mile to her friend's house, where she had some slight refreshment, and proceeded to transact her business in Dalkey.

She did not sleep very well that night, and on the next day she transacted her business, but towards evening she felt a little sick. On the following morning, after passing a rather sleepless night, she complained of much tenderness over the right ovary.

I saw her on the following day; I found her rather nervous, pulse 120, tongue clean, great difficulty of passing water, pain over the right ovary, and the mark of some bruises on the right thigh. The bowels had been freely relieved by a purgative draught, but she had slept little on previous night. I ordered her to be kept quiet, and prescribed bromide of potash. Next morning I found her a good deal relieved, she had slept during the night, but the pulse still remained 120.

On the 4th of March she became somewhat restless and hysterical, laughing loudly without any cause, and said she felt quite well. Her pulse was 126, the temperature was raised 2 deg., her tongue was coated, and her water scanty and high coloured. Next morning, I found her in a depressed and anxious condition. She has been crying much during the morning, and refused to take any food and said she was dying. There was no albumen in the urine, no pain in the head or back, no impairment of sensation, the temperature had fallen to normal, the tongue was again clean, but the pulse was 120.

On March 8 Dr. McSweeney saw her in consultation. She received us rudely, and her answers to all our questions were short and irritable. Her pulse was 120. Her breathing was rapid, her eyes restless, her skin was hot and very dry, and tongue slightly coated. She complained of pain over the left ovary.

On the 10th, the temperature had fallen to 97 deg., the pulse sometimes remaining the same. On the 13th the temperature was again normal, and the pulse 120, and she complained of obscure pains in different parts of the body.

On the 15th she seemed in a high state of fever, pulse 126, tongue much coated, face greatly flushed, eyes bloodshot, and starting at the slightest noise. On the 16th the pulse could hardly be counted, and she was with difficulty kept in bed.

On the 17th she has much improved, and has slept well during the previous night. On the 18th the stomach was

sick, and she complained of pain in the back. From the 19th to the 25th she improved somewhat. On this latter day, Dr. Moore saw her in consultation. Her condition was one of great excitement—her pulse was 100, and the conjunctivæ were congested. On the 27th a slight eruption of purpuric spots appeared.

On April 4, we found her friends very much alarmed, believing that she was insane. She was in a condition resembling melancholic mania. Dr. Robert McDonald saw her in consultation with us on the following day. She had some slight epileptic convulsions then. From this date to the 19th she became gradually weaker. During the evening of the 19th the legs became paralysed, and on the 20th she died.

CASE III.—James Doyle, a man of 30 years of age, was driving a van across the railway near Sidney Parade, when the mail train came up and smashed the cart on which he was seated. He was taken up insensible and conveyed into Jervis Street Hospital where I saw him immediately after his arrival. He then suffered from well marked concussion of the brain and spine, besides some severe contusions in the side. Subsequently, slight myelitis developed, and there was temporary paralysis. He was treated with perchloride of iron and iodide of potash, and gradually recovered. He is now quite well.

CASE IV.—Robert English, a gentleman of 90 years of age, was in a train, when, between Kingstown and Dalkey, on the 27th February, it came into forcible collision with some carriages which rolled down the incline in an opposite direction. He was taken from the carriage in a semi-conscious state, and was seen soon afterwards by Dr. Beatty, of Kingstown, who had him conveyed to Rathdown Hospital, where he was placed in a private ward.

I saw him that night in consultation, and found him in a very nervous condition, with pulse 100, and very irregular; the temperature was 99; the electric excitability of one leg was much greater than the other; he started at the least noise, and remembered nothing of the accident, and could not even recollect how it was that he came to where he then was.

28th.—Very nervous, has not slept any, complains of pain in his back and head, has not passed any water, temperature 97, pulse 110, irregular and intermittent, suffers from headache, and has a wild and anxious look.

March 1st.—Has slept a little, but is in a very nervous condition; has passed about 4 oz. of highly-coloured water.

2nd.—Improved somewhat, pulse still irregular, with hyperæsthesia of one side, headache somewhat relieved, is very restless, and has strange visions when he closes his eyes.

3rd.—Is greatly improved, temperature 98, pulse 90, headache, relieved, has slept well, and is more hopeful.

5th.—Continues to improve, and from this day he became gradually better, and in about three weeks was pronounced convalescent.

CASE V.—Farquharson —, was in the same accident as the previous case, and received a slight blow in the back, and his right knee was somewhat hurt, he felt a little stunned for a few seconds, but soon recovered and was able to continue his journey. I saw him a few hours later. He complained of a good deal of pain over the region of the right kidney, and there was blood mixed with the urine. During the night he vomited twice and slept but little.

On the 28th there was still considerable tenderness over the kidney; there was no increase of temperature, but the blood was still mixed with the urine, and there was a good deal of stiffness in the knee.

March 1st.—Patient somewhat improved, less blood, less tenderness, but knee a little inflamed. On March 8th I pronounced him convalescent.

(To be continued.)

THE great medical charities of Glasgow are in distress again. The Western Infirmary having doubled its accommodation, is more in need of money than ever. The Royal is no less than £10,000 behind this year, and its directors have issued a strong appeal to the public for aid. The annual report of this institution is looked for with some interest. The impecunious condition of these infirmaries seems to have brought the Southern Hospital scheme to a standstill, in the meantime at any rate.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society of Ireland was held on Friday evening, December 9, 1881, in the Albert Hall, Royal College of Surgeons,

Mr. JOLIFFE TUFNELL, F.R.C.S., presided as senior member of the Council present.

Mr. WILLIAM THOMSON, F.R.C.S., Hon. Sec., read the minutes of the previous meeting, which were confirmed.

Mr. F. ALCOCK NIXON exhibited a scapula which he had excised at Mercer's Hospital with a sarcoma weighing altogether 4 lbs. The growth of the tumour was very rapid. It involved the entire scapula, projecting in front of, and below, the glenoid cavity into the axilla. The spine of the scapula, as well as its coracoid and acromion processes, were softened and diseased. The cartilages over the fluid cavity, and the tip of the acromion process, were healthy, and appeared to limit the disease completely. The supra-spinatus muscle was displaced, expanded, and degenerated, assisting with the fascia, which normally covers it, to form a fairly complete capsule for the tumour. The remains of the latissimus dorsi, levator anguli scapulae, serratus magnus, and supra-spinatus muscles appeared healthy. On transverse section the tumour presented to the naked eye a mottled, lobulated appearance, not unlike brain substance. The cut surface varied somewhat in consistence, in some places being quite soft; in others firmer. Below the spine the bone had, for the most part, disappeared, irregular isolated osseous points, united by fibrous bands, marking its former position. It was found on microscopic section to be a small round-celled sarcoma. The patient, a boy, *æt.* 13, has made so far a most satisfactory recovery.

Dr. F. W. WARREN read a paper on

THE THERAPEUTICAL AND POISONOUS EFFECTS OF CARBOLIC ACID,

which will be found on page 22.

The CHAIRMAN observed that the most valuable part of the communication was that with regard to the poisonous effects of carbolic acid, which had become such a popular remedy that it was used almost indiscriminately by nurses. The therapeutical effects were in the hands of the surgeon; the poisonous in those of the attendant. He hoped members would state their experience of the poisonous effects.

Dr. MAPOTHER, referring to the therapeutical effects, was reminded of an illustrious Irishman, Bishop Berkley, who wrote a large volume entitled, "An Essay on the Use of Tar Water." Dr. Warren had mentioned the idea of tar water, which no doubt contained some of the carbon compound produced by the combustion of coal. In the fatal case resulting from the application of carbolic acid to the back, Dr. Warren had not mentioned whether it was applied to a lacerated surface or to the unbroken skin. He had himself used it chiefly in eczema, producing the peculiar discolouration of the urine described, and which was an idiosyncrasy of its operation. About three years ago he ventured to inject a small *nævus* with two minims of liquefied carbolic acid in a tumour on the cheek of a little child, *æt.* 7. Not two seconds elapsed before the child was pale and pulseless; and this was due to the physiological effect of the carbolic acid as a cardiac depressor, and not to the embolism.

Dr. BALL mentioned the case of a man engaged in distilling crude carbolic acid from tar, who consulted him for epithelioma of the scrotum, resembling a wart, and the man stated that horny warts were somewhat common at the works. Three out of sixteen men—the total number employed—had suffered within the last three years. In addition to the crude carbolic acid, other products were obtained from the distillation of tar, but the carbolic acid was the most irritating.

Dr. HENRY KENNEDY, adverting to the question of absorption through the skin, said there were several cases where the simple application of carbolic acid had been followed by serious effects. Every day's experience proved that where it was used extreme caution should be observed. Dangerous symptoms, and even death, had also resulted from its use as an enema.

Mr. KENDAL FRANKS called attention to two therapeutical uses of carbolic acid. Prof. Heister, of Munich, employed it in diphtheria. Recognising the bacteroid cause of the disease, or that it was due to germs, he considered the local application of an antiseptic was the proper remedy. He employed carbolic acid as a spray, playing it into the throat, and the patient was allowed to inhale it freely. This treatment was continued until the urine became nearly black. He did not consider the patient sufficiently under the influence until this symptom was observed. Employing it only in very bad cases of great mortality, the result was strongly in favour of the carbolic acid spray treatment. The second therapeutical use of carbolic acid was as an anæsthetic agent. He had himself used it a good deal in certain throat cases, where strong caustics were required to destroy certain tissues or new growths. Great pain was often caused by the use of strong caustics, but in using pure carbolic acid for the throat he observed that patients seldom complained of much pain, and that the pain passed rapidly off. He used one part in six of carbolic acid in glycerine as a local application immediately after using a powerful caustic, and the result was that the pain, which under ordinary circumstances would last a long time, stopped almost at once, the patient expressing great relief in a few seconds. Having used it largely in this way, he was perfectly satisfied with the effects of it.

Dr. HENRY FITZGIBBON, as a strong advocate of the use of carbolic acid in antiseptic surgery, and as a firm believer in its antiseptic properties, did not think they could be too cautious as to the strength of it. Undoubtedly, as had been argued, it was a dangerous poison, as most active remedies were. The instances of poisoning had resulted from foolhardiness in the use of it, which the first successes in antiseptic surgery led men into. He had often seen, and always regarded as a hazardous proceeding the pouring freely on the peritoneum a spray composed of a solution of 1 in 20 of carbolic acid. In his own study he nearly killed a patient by injecting carbolic solution into the pleura. The patient, a young woman, fell forwards in much the same position as Dr. Mapother had described, and it was with difficulty he restored her to consciousness. That occurrence made him cautious. Still he was as strong a believer as ever in the antiseptic properties of carbolic acid. Keith had had 97 recoveries out of 100 cases of ovariectomy under the carbolic spray—a sufficient proof of its antiseptic properties. He, himself, had had experience of four cases of ovariectomy in the City of Dublin Hospital, and had it not been for the antiseptic properties of carbolic acid, he doubted that in the last two he would have had the success achieved.

Dr. BYRNE said the practice of Listerism being general here and in other countries, it was a question for grave consideration whether, if the dangerous effects of carbolic acid were so common, the operator should use it or not. For his own part, he had always used it in operations; but having regard to the discussion on the subject, his mind was not made up whether he would continue to use it or not. He had used it in four cases of ovariectomy, of which two were successful, and two had died. Those opposed to the use of carbolic acid held that it was particularly irritating to the peritoneum, and that it would be better to carry out all the steps of the operation without the spray. That this would be an advantage to the operator was obvious; but whether it would be so to the person operated on was another question. As to its local application, he had used carbolic acid extensively in the treatment of uterine disease, applying it to the interior, as well as to the outside of the cervix uteri, without any bad results. In dental practice it was commonly used. Again, he would instance an operation in a case of encysted ascites of the peritoneum, where the peritoneum was opened under the influence of the carbolic spray, and the patient recovered, and went on well. In another case of a young woman, who died on the third day after the operation, there was so little trace of inflammation in the peritoneal structures, he was at a loss to account for death.

Prof. WALTER SMITH said that Dr. Warren's observations on the toxicology of carbolic acid related chiefly to three points—the colour of the urine, the detection of carbolic acid in it by tests, and the antidotal treatment. The key to these questions consisted in understanding the elimination of carbolic acid, and the transformation it underwent in the system. The earlier observers held the opinion that

when administered to animals carbolic acid passed through them unchanged, and that the greater part of it was excreted through the urine. However, it was now known that that was not the case. When a large quantity of carbolic acid was taken, about half of it broke up in the system and disappeared, while the other underwent transformation into several, what are commonly known in chemistry as the phenol-forming, substances, issuing in the urine in one or more highly complex compounds. One of these had been identified beyond doubt as a definite conjugated compound, viz., sulpho-carbolic acid. Only the merest trace of free carbolic acid was ever found in the urine, even after the administration of poisonous doses of it. As to the nature of the colouring substance in the urine, they knew little; it certainly was not blood. The brown colour would result from the internal or external administration of carbolic acid. It was possible there might be some difference according to the mode in which it entered the system. As to the detection of it by tests, Dr. Warren had stated the best test consisted in detecting to what extent the sulphates were absent from the urine, but, strictly speaking, the chloride of barium test fails to detect the sulphates which are rendered latent, as it were, sulpho-carbolsate of barium being soluble. The brown colour was certainly not due to indican, in respect of which body our knowledge has much advanced. Indican, as such, does not occur in the urine, and the source of all the indigo-forming bodies found in the urine, is the change effected by pancreatic digestion. One of the most delicate tests for carbolic acid was Landolt's. On the last point, as to the best antidotal treatment, if in poisoning the carbolic acid could be converted into a sulpho-compound, the poison would be neutralised, and the danger lessened. One of the best antidotes, if not the best, would be the free administration of dilute sulphuric acid, or some other soluble sulphate.

Dr. COLE, of San Francisco, said he was invited to be present, not to hear this particular discussion, but to be interested in whatever question came before the Society, and with the distinct understanding on the part of all his friends, that he was an open, avowed, and uncompromising enemy of Listerism. He did not think, therefore, that it was exactly the thing for him to speak, surrounded, as he was, by so many earnest, honest, conscientious advocates of Listerism. But since he had been called to his feet, and it being a quality of the American character to shrink from no responsibility, he would speak to the question. In his own practice, he had had, perhaps, as extended observation of the effects of carbolic acid used surgically as any other man of whom he had knowledge. In the medical administration of it for disease he had no experience. As to its surgical use in the form of spray applied to ulcers, abraded surfaces, open cavities, serous membrane, and mucous, he yielded the result of his observation to that of no man. With the evidence staring him in the face from every civilised people of the world—from France, Russia, Spain, Portugal, England, Ireland, everywhere that there was civilisation and intelligent surgery—that carbolic acid was the great conservator, the great sheet anchor, he was naturally forced to bow submission. But what was the result of his observations? First, in his experiments he found what he believed justified his opposition to it; and he could not now be convinced of its efficacy even by Mr. Lister in his recent defence; for he was placed on the defensive. Dr. Fitz-Gibbon had referred to Mr. Keith, whose integrity and sincerity could not be questioned, and said he had had 97 recoveries out of 100 cases of ovariectomy under Lister's method. But he had previously had 90 out of 100 before he ever resorted to Listerism, and then he reported 97 recoveries in the succeeding 100 cases. Was Dr. Fitz-Gibbon disposed to accredit anything to the experience Keith had acquired? Was it not possible that the experience of 100 additional cases would account for the increase of 7 per cent? But, apart from that, in the language of Mr. Keith himself, before the Surgical Section of the International Congress at London, "It is true that I had 80 consecutive cases of success under Listerism, but too many of those came near dying, and in the succeeding 25 cases I lost 7, and yet practised Listerism." Three of them died of unquestionably carbolic poisoning, one of unquestionably renal trouble, which was incidentally or directly due to the effects of carbolic acid, and one from septicæmia; the others he did not remember. It seemed to him that the craze of carbolic acid was, as in other transactions of life, due to

the direction of fashion, just as a woman was influenced in the style of her bonnet or dress. Or, like a flock of sheep following the black one, or the bell wether, as the case might be. Personally, he respected Mr. Lister. Who could fail to do so? Mr. Lister was earnest, honest, and conscientious in what he gave to the world; but he was absolutely mistaken, and he tacitly admitted the fact when, in reply to Mr. Keith, he spoke in defence of his position. In his written and now published remarks, he did not stick closely to the text of what he had said in reply to Mr. Keith. That he should have been given an opportunity of bolstering himself was quite proper to a man, who, having taken the medical world as it were by storm, became the leader of such a movement. Mr. Lister, in his remarks, admitted distinctly that he did not have the results which, in the beginning, he had anticipated from the spray; and, in the experiments he had been making, he had nearly as many bacteria when it was mixed with blood as when there was no such admixture. In his own experience of ovariectomy, every woman with whom he employed Lister's spray had died. True, he had not had the experience of Spencer Wells, or Keith, or even of Lawson Tait. But of the 16 cases in which he had operated he used the spray in three, and in these under protest, saying to the gentlemen assisting him, "You know my position with regard to carbolic acid as an antiseptic, and as to its influence upon those cases, i.e., its possible effect on the delicately organised membrane of the peritoneum." For fourteen days after the operation his hand was rendered numb and unfit for use. The powerful effect of carbolic acid on the serous membrane was well known. In his cases, as he had said, the patients died, and he believed he had himself killed them; but he did it innocently, because the evidence was so overwhelmingly in favour of carbolic acid, that he felt, if he neglected to employ it, he would have been at the mercy of the profession. It would be said, had he utilised all in his power, the results might have been different. Thus he was forced to do it. But now remained the question whether he should ever operate again, and use carbolic acid or not? If he ever did, no carbolic acid would be used. As to the use of carbolic acid in general surgery, the whole system of Listerism was simply cleanliness, which was next to godliness. Exercising the cleanliness observed in the employment of carbolic acid, they would have with water quite as good results.

The CHAIRMAN asked were there any conditions in the three fatal cases which did not occur in the other cases?

Dr. COLE said there was no reason why death should have occurred except from carbolic acid, and the symptoms that preceded death indicated poisoning.

The CHAIRMAN—But there were no conditions in regard to the operation in these cases different from the others?

Dr. COLE—Nothing specially bad.

Dr. DARBY objected to the word "septicæmia," because he could get nobody to tell him what it meant. There was no such thing as putrid or rotten blood circulating in the human living body. At the hospitals in London, Dublin, Edinburgh, Paris, and elsewhere, he asked to see a case of septicæmia, or could the doctors tell him what it was.

Mr. THOMSON rose to order, pointing out that Dr. Darby was drifting to a subject not before the Society.

Dr. DARBY said chloride of lime was a better germicide than carbolic acid, according to the experiments at Netley. No surgeon would use chloride of lime alone. Carbolic acid was a good application in ulcers and sores, but he did not think chloride of lime would be found so. He had been asked what he meant by life when he spoke of vital influence.

Prof. BENNETT rose to order, and said the discussion was with reference to the toxic effects of carbolic acid, not with reference to the nature of life.

Dr. DARBY thought the whole point turned on the effect of carbolic acid as a germ-killer. He would not, however, persevere with his remarks.

Prof. BENNETT, speaking from considerable experience of the use of carbolic acid in general surgery, said he never saw any serious toxic results from carbolic acid as an antiseptic in general surgery, or even in abdominal surgery. As antiseptic surgery grew, carbolic oil came into practice, being used extensively in burns, so that it was not uncommon to find the treatment in the first instance consisted of covering the burn with carbolic oil. He had seen this done without bad effects; but no later than last month he had seen two children poisoned seriously by such dressing applied by the nurses without waiting for directions. The strength of the carbolic

oil was one to eight, and it was no wonder a child should be comatose and vomiting. Therefore, it was necessary to protest against the slipshod use of an acute remedy. Almost every mother of a family thought carbolic oil was a good treatment for any sort of wound. In a young child absorption readily took place, and the child was poisoned. For burns the acid was too stimulating, and overworked the surface.

Mr. WHEELER questioned the accuracy of Dr. Warren's statement that it was Lister who first introduced carbolic acid into surgical practice. With regard to poisoning by carbolic acid, he had a short time since read a paper before the Society, detailing cases he had himself treated by Listerism, and by antiseptic surgery, and he then proved that, of two cases, one was poisoned, and the other so effectually as to die from carbolic acid. In one case Syme's amputation of the foot was performed, and in the other ovariectomy. It was a fair hypothesis that Keith did not use carbolic acid in a slipshod way. Dr. Cole was correct in his recollection of what Keith had said at the Congress.

The CHAIRMAN interposed, and intimating that the hour for adjournment had arrived, asked was it proposed to conclude the debate, or adjourn it to a future meeting.

Mr. WHEELER moved, and Mr. O'GRADY seconded that the debate be adjourned to a special meeting.

Mr. RICHARDSON moved as an amendment an adjournment to the next ordinary meeting of the Society.

Mr. BENNETT seconded the amendment, which was put and carried by a majority.

The Society then adjourned.

REGISTERED FOR TRANSMISSION ABROAD.

THE

MEDICAL PRESS AND CIRCULAR

Is published every Wednesday morning. Price 5d. Post free, 5jd.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6

IF PAID IN ADVANCE 1 1 0

* Post-office Orders and Cheques to be drawn in favour of—

A. A. TINDALL, 20 King William Street, Strand, London, W.C.

A. H. JACOB, 8 Molesworth Street, Dublin.

Agents for Scotland:—

MACLACHLAN and STEWART, South Bridge, Edinburgh.

A. and W. STEINHOUSE, Hillhead, Glasgow.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hauteville, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Philadelphia, by Dr. BRINTON, post free in advance, 5j dollars (£1 2s. 6d. per annum); or direct from the Offices in this country for the same amount, if remitted by International Post-office Order.

ADVERTISEMENT SCALE.—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.

Small Announcements of Practices, Assistancies, Vacancies, Books, &c., of seven lines or under, 4s. per insertion; 6d. per line beyond.

Considerable reductions are made from the foregoing scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 11, 1882.

THE TREATMENT OF RHEUMATISM.

PROBABLY no special form of treatment of any disease has attracted so much attention, or has been so universally followed, as that of rheumatism in its non-chronic states by the salicylic method. It is now barely seven years since the employment of salicylic acid as a remedial agent for the relief of acute rheumatic pains was pub-

lished to the profession, and already the literature of the subject has attained proportions rightfully denominated vast. It is true that hitherto wide discrepancies of opinion have been registered concerning the efficacy of the drug, authorities being found both to advocate and condemn its use; but it is proper to urge in connection with this conflict of belief in its powers, that even at the present time we are not in a position to say definitely in what form, or under what invariable conditions, it can be safely administered in every case of disease. Discussions on the effects produced by it, on the evils induced through its action on the system, and on the benefits to be expected from it, have from time to time taken place, and particularly at the last three meetings of the Medical Society of London. In 1880 Dr. E. Headlam Greenhow, while holding office as President of the Clinical Society, read before that body a lengthy and valuable paper, in which he presented an exhaustive analysis of a series of fifty-three cases of acute rheumatism occurring in his practice at the Middlesex Hospital. The discussion that followed was a sufficient indication of the importance attached to the question by the profession, but it was in a measure unsatisfactory owing to the want of definiteness respecting the views expressed by various speakers, and from the fact of a preponderance of objection to the use of salicin on account of the serious after-consequences presumed to arise from its employment. Since that time occasional papers and articles have been contributed to societies' proceedings and the medical press on the same subject, but all these are lost sight of behind the lengthy and invaluable series of communications to the medical society referred to. We propose to devote attention in the present article to the results therein arrived at.

Dr. Francis Warner concludes, from observations of 190 cases of rheumatism, acute and sub-acute, in all of which a temperature exceeding 102° F. was recorded, that "salicin lessens the duration of the pyrexia and joint pain." The average duration of pyrexia in these cases was five and-a-half days, while under treatment of 7 cases without salicin the average duration extended to 13.8 days. Similarly, pain persisted for 5.3 days under salicin in 277 cases, and for 9.2 days in 67 cases treated on other lines. Finally, the average length of confinement to bed of cases treated with salicin was 19.5 days in 342 instances, and in 211 without salicin it amounted to 23.5 days.

An important point, however, now remains to be considered, viz., in what degree are heart affections influenced under the two modes of treatment? and on it Dr. Warner's conclusions differ only slightly from those of previous observers. He records that in 13.9 per cent. of the patients submitted to salicin treatment there was development of heart symptoms, while these were exhibited in 14.9 per cent. of those otherwise treated.

Next we will take the statement of Dr. De Haviland Hall, whose conclusions are based on an examination of 55 cases of acute rheumatism in the wards at Westminster Hospital during 1880. Salicylate of soda was the drug employed in all those cases where this treatment was adopted, 38 in number; in 14, heart complications occurred, while in five of the remaining 17 similar sym-

ptoms were developed. Dr. De Haviland Hall expresses himself in favour of salicylate treatment, which he avers tends to reduction of time during which fever and pain persist; and in reference to the heart complication he distinctly admits the superiority possessed by it, on the ground of the more acute nature of the cases in which it is resorted to. Toxic influences ascribed to the salicylate do not, in his experience, weigh at all heavily; salicinism occurred in eight cases, but left no permanent effect, and the general tenour of his observations is distinctly favourable to the employment of the drug in acute cases.

Dr. Isambard Owen tabulates 210 cases of acute and sub-acute rheumatism treated in 1877 and 1878 in St. George's Hospital; the results pointed by these are markedly favourable to the salicylic treatment. Comparison of cases treated thus, with those in which alkaline remedies were adopted, shows that under the former plan the average duration of pyrexia and pain was $3\frac{1}{2}$ to 4 days, while under the latter the average of pyrexia was $6\frac{1}{2}$ days, and of pain 8 days. Dr. Owen arranges his salicylic cases in three tables accordingly, as the initial amount of drug prescribed exceeded three drachms, was equivalent to 2 drachms, or did not exceed $1\frac{1}{4}$ drachms per diem. The toxic effects produced were found to be in proportion to the size of the doses administered. Thus, in the first-class, they followed in $23\frac{1}{2}$ per cent. of the cases; in the second-class, in $13\frac{1}{2}$ per cent.; and in the third-class in $10\frac{1}{2}$ per cent.; and a hope is expressed that these embarrassing consequences may, in the future, be avoided—a not impossible event. The average days of illness, again, under each mode of treatment affords an interesting study. Where the larger quantities of salicylate were administered, it reached 6 days from the commencement of treatment. It was a similar time in the second-class, and 7 days in the third-class; while under the simple alkaline treatment it reached $10\frac{1}{2}$ days. Heart affections were observed in several cases. Præcordial friction was found in four cases treated with full doses of salicylate, and in one case treated with full doses of alkali; but Dr. Owen infers that in all but one case the condition preceded treatment. Albuminuria did not seem to be a consequence of the treatment in any of the cases. There was no occurrence of hyperpyrexia in any instance, and no death was recorded. Here, too, then, abundant evidence is afforded of the superiority of the new treatment over the older method, and testimony to the freedom from dangerous complications, of which suspicions have been freely and frequently expressed in the immediate past.

Dr. Donald Hood, however, of the West London Hospital, in a careful analysis of 1,200 cases of acute rheumatism occurring in persons under 35 years of age, arrives at conclusions, which, substantiated as they are, must be very carefully considered in their bearings on the question at issue. He also demonstrates that patients taking salicylate lose their pains more quickly than those who do not take the remedy. And this is further borne out by Dr. Hilton Fagge's results. Against this, however, must be placed the fact that patients so treated relapse with far greater frequency than when other forms of

treatment are followed. They thus remain, in the aggregate, a longer time in the hospital, and, Dr. Hood asserts with Dr. Fagge, are left feeble and exhausted after the use of the drug. Again, with respect to cardiac complications, Dr. Hood finds that the proportion of those affected under one or other form of treatment is much about the same; and concludes that, "What little advantage there is does not appear to be on the side of the salicylate treatment." Further, he insists that any remedy claiming to be of "specific" effect in acute rheumatism must be capable of controlling heart disease; and this power is manifestly wanting to salicin.

Dr. Hood's tables are very valuable; they are incontrovertible, but they are also disappointing. They practically illustrate the uncertainty that still surrounds the whole question, and they cannot be overlooked in the present aspect of the controversy. It may, of course, be said that he attaches undue importance to certain signs and appearances; but with the data he supplies to refer to, it will be difficult for his opponents to rebut his evidence, or to refute the unexpressed conclusion that contrary decisions to those he expresses are untenable. Out of 1,200 cases he has summarised, it is true that only 350 were subjected to the treatment now on its trial, while 850 were otherwise treated. Nevertheless, it remains that even this number is a higher total than any advocate of salicin has been enabled to produce; and the results exhibited in the tables suffer nothing by comparison with other statements. It is, undoubtedly, in the conclusions drawn by him that Dr. Hood's position is a strong one, and until they are met by contrary evidence they will continue to demand the careful attention of every practitioner.

The influence exerted by impurities in salicylic acid forms the subject of a short paper by Dr. J. K. Fowler, who ascribes to them the toxic effects following salicylic treatment; and suggests that employment of a pure drug, together with properly-arranged wards, maintained at a sufficient, equable temperature, would ensure a greater amount of success in the treatment of rheumatism by such means.

Dr. Sidney Coupland contributes an analysis of 84 cases admitted under his care into the Middlesex Hospital during two years. His conclusions are favourable to the use of salicylate of soda in their treatment, and he enters at length into a consideration of the various details.

The lesson taught by this discussion is a most useful and important one. There is a common agreement that certain definite effects are produced by salicin in cases of acute rheumatism, and that these effects may be fairly anticipated to follow from its employment. Whether, however, the advantages of speedy reduction of pain and fever are absolute, or are counterbalanced by equally weighty disadvantages, is the point on which as yet it is impossible to say a decision has been arrived at. We cannot conceal from ourselves that the advocates of salicin all seem determined to accept its good qualities, and to ignore its potentiality for evil; but with the evidence, and the deductions from evidence, afforded by Drs. Hilton Fagge and Dalton Wood are we, it is fair to inquire, justified in regarding the matter as other than

sub judice? Honestly, we think not; and honestly, too, we believe that further and more complete and extended investigation—especially of the complications set up by it—on the effects produced by salicin, are required to enable a reliable estimate of its character as a remedy to be formed.

EXPURGATION OF THE MEDICAL REGISTER.

THE utter incapacity and worthlessness of the General Medical Council for the discharge of this, amongst other duties entrusted to them, is brought under special observation just now.

In Glasgow, a quack, named Levenson was put out of court with ignominy by the sheriff, because of his traffic in obscene pamphlets, and from the evidence taken, it appeared that the name of this fellow had been removed from the Medical Register in 1875; and afterwards reinstated by the General Medical Council, and maintained therein, until it was finally taken out at the instance of those of the profession who had more care for its decencies than the General Medical Council. Again we read that Dr. Lamson, who is now under trial for the poisoning of his relative, had been publicly convicted of trading on false diplomas, and pretending to have degrees which he never possessed. This fact, with the full evidence of his guilt in the matter, was brought under the notice of the General Medical Council, but *more suo*, it shirked the trouble and responsibility of removing his name from the Register. Instead of doing so, it passed on the matter to the Colleges of Physicians and Surgeons of Edinburgh, whose Licentiate Lamson was, and of course, those bodies took not the least notice of the matter, and consequently Dr. Lamson remains a registered practitioner to this day.

Now it must not be supposed that the General Medical Council has the shadow of an excuse for thus refusing to perform its duty.

The 31st Section of the Medical Act declares that, "If any registered Medical Practitioner shall, after due inquiry, be judged by the General Council to have been guilty of infamous conduct in any professional respect, the General Council may, if they see fit, direct the Registrar to erase the name of such Medical Practitioner from the Register."

The Council, however, always, unless forced to do so by some extraneous pressure, refuses to make "due inquiry," and, as a matter of fact, seldom removes a name until the body which granted the License has first annulled the qualification, and notified its having done so. Thus, if a disreputable person has three registrable licenses, he does not disappear from the Register, and is not disqualified to practise as a qualified medical man, until each of his licensing bodies separately expel him.

It is evident that the medical profession will never be free from the stain of public association with such practitioners, as long as the Medical Council exists in its present form. That body has deliberately refused to expunge the names of felons who have served their term of penal servitude, and it is now seeking from Parliament new powers to gloss over any or every offence which it may be pleased to consider "trivial." We hope no such

powers will ever be granted; and we look with hope to the pending rebuilding of the Council in which, we hope that the prevalent mistake will not be committed of using up old materials.

THE DENTAL DIPLOMA TRADE.

WE wonder how long the sale of collegiate licenses in dental surgery to hair dressers, tobacconists, and druggists' assistants, will be allowed? At present the Colleges of Surgeons of Edinburgh and Dublin, and the Faculty of Physicians of Glasgow, are doing a roaring business in dental diplomas, and, so far from showing a disposition to cry halt, they are advertising, far and wide, their readiness to take the money of anyone who likes to buy a parchment with which to decorate his shop. Our readers know already that, when that unhappy blunder, the Dentists' Act, passed, a multitude of persons were coopted as dental surgeons, and placed on the roll of legalised practitioners, the great majority of whom did not make any pretence of knowing anything whatever about dental anatomy or surgery, and did not set up for any higher degree of professional skill than is involved in pulling a nail out of a board.

The great majority of the new-made dentists, indeed, never had had the least notion of being recognised as dental surgeons, and they could hardly believe in their new dignity when they awoke to find themselves ennobled by admission to the dental roll.

There is no exaggeration in this statement. From the Dental Register of 1881, we find that 5,266 persons are entered therein. Of these, 565, or one in ten, has been examined, and found to know something of the art, while the remaining nine-tenths (4,698 in all), are uncertified pretenders to dental knowledge. Of this latter class about 2,000 are persons who, with or without knowledge of the subject, devote themselves to dentistry as a means of livelihood. The remaining 2,600 persons are, confessedly, hair-dressers, barbers, druggists' assistants, and other persons who would not, if they could be asked the question, lay claim to the minutest portion of dental knowledge, skill or experience. Several of them, indeed, have been questioned by the General Medical Council, and have, one and all, candidly admitted their total ignorance of the subject.

It was bad enough that the profession of dental surgery should be degraded by the admission of these 2,600 persons, but the injury which the profession sustained thereby was somewhat mitigated by the fact that every one in the profession knew that dental registration was rather a proof of ignorance than of competency. The greediness of the licensing bodies, however, is likely to aggravate greatly the evil to which the Dental Act gave origin. When the Act passed, the London College of Surgeons—to its credit be it said—steadfastly resisted all importunities to give its license in dental surgery to anyone whose respectability and whose competency it had not tested, and still, even though the Medical Council intimated that it would not object to the sale of diplomas, the London College has refused to engage in the trade. The Colleges of Edinburgh, Glasgow, and Dublin, however, were not so punctilious. The two Scotch Colleges at once

intimated to the General Medical Council their readiness to take the money of every one of the 5,000 unqualified men on the Dental Register, and they have lately intimated that they have no intention to cease from so paying a business. The Irish College of Surgeons took a different course—it declared that it would keep its doors open for two years from the passing of the Dental Act (*i.e.*, about one year from the holding of the first examination), and for not a moment longer, and it sent to the General Medical Council regulations formally adopted by the College, which declared that after the first of August, 1881, no one should be granted a diploma until he could show that he had studied dentistry according to a proper curriculum.

This decision the Council of the College has recently, we regret to hear, gone back from, without even the approval of the Medical Council, to whom it had given its previous promise, and, in conformity with this resolve, a new dental examination is advertised, to which the whole of the *canaille* of the Dental Register will be admissible if they can get the signatures of two or three practitioners of their own class to their letter of application.

On the part of the Licentiates and Fellows of the Irish College of Surgeons we emphatically protest against the issue of diplomas to such people, to be hung up, no doubt, in the tobacconists' or barbers' shop, alongside the advertisement placards of "Bristol Birds-eye," or the "Marvellous Hair-Restorer," and we utterly repudiate the theory that the College is justified in departing from its engagement with the General Medical Council, or in granting licenses on any subject to persons of whose education in the subject no guarantee exists.

On behalf of the profession of dental surgeons, we would suggest that it will be needful for them to protest against the collegiate decoration of persons of this class with whom the Dental Act has overwhelmed them. The British Dental Association is, no doubt, able to take care of itself, and we have confidence that it will do so, but, it is, at least, right that we should let the Fellows and Licentiates of the three Colleges, and the more respectable dental surgeons know what is being done towards a further degradation of their Colleges and their profession.

Notes on Current Topics.

The Convalescent Home for Infectious Diseases in Dublin.

THE praiseworthy movement for establishing an institution in Dublin to which fever patients might go before returning to their own homes, has come to an unsuccessful conclusion. After repeated vain attempts to galvanise the benevolent public to an appreciation of the necessity for such an hospital, the Executive Committee was obliged to meet last week and abandon the scheme. It was resolved:—"That this Committee, acting in accordance with the power given them by the public meeting of subscribers held on December 8, 1881, do accept the offer of the Governors of the Cork Street Hospital, as contained in their letter of June 2, 1881, and do hereby authorise the Finance Committee to collect all outstanding subscrip-

tions and discharge all claims on the fund, and, after audit, hand over the balance to the Managing Committee, House of Recovery, Cork Street, for the purpose of increasing the accommodation in their institution for patients recovering from infectious diseases."

It is much to be regretted that the excellent object aimed at by the promoters of this movement could not be attained, but the reason of the failure is not far to seek. The Dublin public felt that this convalescent home—if necessary—ought to be provided at the expense of the citizens generally, and not by the efforts of the few generous people whose money is always ready for a good work, but the Dublin Corporation saw no chance of a political row likely to arise out of such a movement, and did not anticipate that a convalescent home would afford much opportunity for family jobs, so it received the proposal coldly. The Dublin Town Council could afford to spend the money which a magnificent convalescent home would cost, as a subsidy to enable persons of insignificant commercial position, but rancorous political views, to undertake the Lord Mayoralty; but it would not trouble itself with the spread of infectious disease in the city, except, indeed, so far as to try to compel the doctors to do the work for nothing.

We regret the failure of the attempt to establish the Home, but we think the promoters must have known little of the Corporation when they undertook the hopeless task of interesting them in the sick poor.

Snakes.

FOR a time the belief was entertained by a comparatively small number of medical men in India that in permanganate of potash there existed an antidote against the venom of poisonous snakes. Experiments had shown that the natural venom, when immersed in the permanganate solution, became thereby deprived of its particular properties, so that when afterwards injected into the living tissues its usual effects were not produced. On the other hand, however, it was found that after the actual poison had been injected and the system had begun to manifest the ordinary effects of the poison, the use of the "antidote," whether by subcutaneous injection or otherwise, had no power to check them; in fact, that the preparation was no antidote at all. In the Indian papers of the day the subject is still being discussed. According to one writer what *may* be an antidote against the poison of one kind of snake *may* not be so against that of another. For example, the poison of the cobra is a neurotic, that of the *Daboia Russelii* is a septic. It is therefore conceivable that the agent which *would* prove an antidote to the former *would* fail to exercise any influence upon the latter. Reference is made to experiments performed by M. Lacerda in Brazil. The poison used in such instances was not that of the cobra—at least, such is the statement made. Therefore, it is added, although he *may* have discovered an antidote to the poison with which he did experiment, it would be only fair to await the decision of the other experimentalists who may have the advantage of performing experiments with the same species of snake as that used by M. Lacerda before condemning his suggestions. It does not follow that because some experimentalists have failed to obtain certain results,—such

results are unattainable. *Supposing it should be found that the effective subcutaneous injection of permanganate of potash in a stronger solution than has hitherto been used had the power of neutralising the cobra poison, the fact will be of considerable importance in the treatment of cobra poisoning, though it is undoubtedly true that any treatment of snake poisoning calling for the exercise of more than the lowest standard of intelligence can have but limited application in India, at least for some years to come. Should permanganate of potash prove to have only the limited power of destroying the poison living in the tissues without materially injuring the part, we may not only save life, but also the limb. Much yet remains to be done before any decided opinion can be given as to the nature of permanganate of potash in cobra poisoning, viper poisoning, and the poisoning by other Indian snakes. The words italicised in the previous remarks indicate the nature of the data on which the conclusions are drawn with regard to the assumed effect as an antidote of permanganate of potash in cases of bites by poisonous snakes in India. The actual result indicated is, that this so-called antidote is an ineffectual in cases of natural poisoning as each and all of the remedies that, from time to time, appear as so many recently discovered specifics in such cases have hitherto proved in reality to be.*

Hip Deformity in Coxalgia.

At a recent meeting of the Société de Chirurgie, M. Verneuil observed that he had treated a young girl, *æt.* 9, for coxalgia, by complete immobilisation of the joint, for a period of three years and a half; she was cured without the slightest deformity remaining. About one year later he saw the young girl, and found very pronounced deformity, with apparent shortening, elevation of the pelvis, but without any trace of sensibility or of inflammation about the joint. Remembering the cases cited by Valtat in his thesis, where permanent progressive flexure at the knee, through paralysis of the triceps, without arthritis, ensued after prolonged immobilisation of the joint, M. Verneuil sought if such could happen for hip-joint. And in effect he found a complete paralysis of the gluteal muscles in this young girl. The deformity was due to the tonic contracture of the psoas, the adductors and the sartorius, with an elevation of the pelvis difficult of explanation.

This case demonstrates, like many others at the knee and hip, that deformity may supervene late in the disease, without inflammatory symptoms, solely on account of the paralysis of certain groups of muscles and the tonic contraction of their antagonists.

M. Verneuil has sometimes, in such cases, obtained definitive cure by electricity, and he considers that it is to the contraction or paralysis of certain groups of muscles that the deformities (*attitudes vicieuses*) at the hip-joint are due, in coxalgia. The abduction, external rotation and apparent lengthening of the limb, observed at the *debut* of coxalgia, are the result of the contraction of the iliacus and the gluteal muscles; the external rotation, adduction and shortening through elevation (*ascension*) of the pelvis, which supervene later, are due to the paralysis of these same muscles. The contiguity of these muscles to an inflamed joint explains the contraction at

the commencement of the disease; later on they become atrophied, and we have the deformity of the second period.

The Curability of Uterine Displacements.

DR. MUNDE, editor of the *American Journal of Obstetrics*, draws the following conclusions from 895 cases that have come under his care:—1. Displacements of the uterus are permanently curable in the large majority of cases only when recent, or when a complete tissue metamorphosis, as occurs during pregnancy and after parturition takes place. 2. Chronic cases (of more than a year's standing) are but rarely curable permanently, except occasionally under the last-named circumstances. Apparent cures reported by some authors and witnessed by many physicians, soon show themselves to have been but temporary. 3. Pessaries form unquestionably the most practical, rational, and (temporarily) the most efficient means of treating uterine displacements. Cures are but rarely accomplished by them. 4. Medicated, chiefly astringent, tampons, intelligently applied every day by the physician, give the best chances for permanent cure. This is particularly true of prolapsus, but holds good for all forms. 5. Electricity locally applied deserves more extended application. 6. All methods should be persevered in for months and years before success is to be expected.

Medical Society of London.

THE Lettsoman Lectures at the Medical Society of London, on the Diseases of the Testicles and their Coverings, will be delivered this year by Mr. H. Royes Bell, of King's College Hospital. The subjects of the lectures will be: 1. January 9th. Varieties and Treatment of Hydrocele: Symptoms and Treatment of Hæmatocele: Elephantiasis Scroti: Epithelioma, and other affections of the Scrotum.—2. January 23rd. The Anatomy of the Testicle: Development of Spermatozoa: Abnormal Situation of the Testicles: Varicocele, and its Treatment: Nervous and Functional Disorders of the Testicles: Tumours and Imperfections of the Spermatic Cord.—3. February 6th. Acute and Chronic Orchitis: Tubercular Disease of the Testis: Benign Fungus of the Testicle: Simple and Malignant Tumours of the Testicle: Castration. The lectures will be illustrated by casts, diagrams, microscopical, and other specimens.

Indian Medical Items.

THE cholera wave, which lately swept over Western India with such disastrous effects, has passed on to the Madras Presidency, and is causing heavy mortality in some districts. In Tanjore about a third of the persons attacked are said to have died. From the town of Trichinopoly, after having prevailed with severity, the epidemic is stated to have penetrated into the interior of the district.

The Sanitary Commissioner with the Government of India, was recently in the Hyderabad districts on a tour of inspection. Details are not given as to the precise nature of his "inspection," nor as to the existence of any particular necessity for it. Has not "sanitation" in India of late run a little towards the border-line of extravagance?

Death of Dr. Draper.

On Wednesday last there died, at his residence on the Hudson River, Professor John William Draper, M.D., LL.D.—the well-known physiologist and philosopher, Dr. Draper—whose name is familiar to every student of the history of science through his "History of the Intellectual Development of Europe," and the yet more universally read "Conflict between Religion and Science," has also done much for the study of physiology by the publication of his inimitable "Treatise" on the subject. The late professor was born at St. Helens, near Liverpool, in 1811, and was educated at the University of London, whence, in 1833, he proceeded to America, graduating as M.D. in 1836 at the University of Pennsylvania. Shortly afterwards he received the appointment of Professor of Natural Philosophy, Chemistry, and Physiology in Hampden-Sydney College, Virginia, changing this post three years subsequently for that of the Chair of Chemistry and Natural History in New York University, where, in after years, he became President of the Scientific and Medical Departments. Dr. Draper's most recent labours have been devoted to his favourite pursuit—chemistry, experiments in spectrum analysis being among the last work performed by him. He will probably be best remembered, hereafter, by the book named above, although he was for many years a frequent contributor to scientific periodical literature. His "Treatise on Human Physiology" has achieved a large amount of success both here and in America, and the estimation in which it is held is still considerable, even though it differs in many respects from more recently published works. Dr. Draper's two sons are honourably known as scientific workers—one as a chemist, the other as an astronomer.

Licensed Infection.

It is difficult to write temperately of the utter want of caution exhibited by the officers of the Local Government Board in dealing with the men who obstinately and ignorantly persist in defying the worst dangers to be apprehended from the presence of small-pox in the midst of crowded towns. According to a recent note from the Local Government Board to the guardians of Evesham, it is henceforth to be a rule not to institute prosecutions against persons already fined for resisting the vaccination law in respect to their children. The effect of general adoption of this regulation, it need hardly be said, will be illimitable multiplication of cheap martyrs, who, at the expense of a single fine, will willingly purchase the state license to propagate disease by means of their unvaccinated offspring. That this is the consequence to be feared from Mr. Dodson's ill-judged temporising with anti-vaccinating professors, proof is already forthcoming, Mr. Ellison having recently refused to visit a parent with the punishment rightly incurred by his resistance of the law, on the ground that the Local Government Board had declared against repeated fining of the same individual. Under these circumstances, there is too much reason to dread that recent experiences will assuredly be recalled to mind by the outbreak of fresh epidemics of small-pox; and, as tending in this direction, the Registrar-General's weekly returns point ominously to the same conclusion. Should

the worst occur, however, there will be no difficulty in accounting for the circumstances, since all that could be done officially to help it on is being faithfully performed.

The Late Dr. R. J. Harvey.

We are glad to record that the memory of this distinguished medical *savant* is not to be forgotten. A large and influential meeting of the profession was held in the hall of the King and Queen's College of Physicians yesterday, for the purpose of erecting a testimonial, recording the esteem of his brethren towards him whose placé can hardly be filled.

Dr. Harvey was not a mere "butterbred student;" but devoted his life and his shining abilities to those branches of physiological research which never pay the investigator, but yet, are of priceless advantage to the practical physician, whose art could not advance without them. Few have the ability to pursue such studies, and fewer still are in a financial position to so occupy themselves in a country where science is practically unendowed. Such men are plentiful enough in Germany or France; and it is to this circumstance that the greatness of their medical schools is mainly due. In Dr. Harvey's case, talent and competence coincided; and we are glad to see that this is remembered.

House Explosions.

THE recklessness with which people still continue to carry naked lights into rooms filled with escaped coal gas, is nothing less than marvellous in face of the numerous warnings that have been given in former accidents. Another of these results of carelessness occurred on Friday last in a block of recently finished, but uninhabited, buildings, known as Victoria mansions, and situate in Victoria Street, Westminster. Fortunately no one, not even the workman who carried the candle which ignited the gas, was injured, but very considerable damage was done by the force of the explosion, and had the house been inhabited, it is likely that serious injuries would have been suffered by the inmates. It cannot be too strongly impressed upon the public that the slightest odour of coal-gas in a room or house should be the signal for immediately adopting measures of the utmost caution in order to discover the extent and source of the escape. Nor, until free means of ventilation have been for some time in action, should any attempt be made to approach the place of escape with a light, or bad consequences will at once ensue. This warning should be often repeated.

Hospital Sunday in New York.

THE custom of collecting money in churches on one day in the year in aid of the hospitals, which was introduced into New York from London, is gaining ground on the other side of the Atlantic. Hospital Sunday in New York was held on Christmas Day, and the collection amounted to 44,000 dols. In 1879, when the movement was first started, the amount realised was only 26,000 dols.

A NEW use for ergotine has been found by Dr. R. W. Millican, who states that he has found it to relieve the heat and pain and to reduce the swelling of facial erysipelas, and to cause the disease rapidly to subside.

Anti-Vivisection at Birmingham.

THE early proceedings of the Council of the newly opened Mason Science College at Birmingham will hardly convey to the scientific mind a likelihood of valuable physiological studies being carried out there, unless indeed, a speedy change be initiated in the spirit by which the decisions of the governing body seem to be ruled. By a recent decree this body refuses to grant the request made by Dr. Haycraft, Professor of Physiology to the College, that he might be allowed to make application for a license under the Experiments on Animals Act. It may be, of course, the combined wisdom and intelligence of the authorities of the Mason Science College have discovered a method whereby the study of physiology may be conducted, and research prosecuted without those natural aids which have hitherto been found essential. Otherwise it is only possible to conclude that Birmingham's appreciation of the means and aims of scientific inquiry is as narrow and ill considered as that which distinguishes the unthinking crowd ruled over by the gentleman who addresses weekly advertisements to Professor Owen. It is to be hoped that the Science College will ere long be relieved from the ridiculous position it now occupies in the eyes of all sensible persons.

University College, Liverpool.

THE ceremony in connection with the opening of this institution is fixed for Saturday, the 14th inst., at St. George's Hall. The Earl of Derby will preside on the occasion, and the Principal (Professor Rendall) will deliver an inaugural address. The lectures and classes will commence on Monday, January 23rd. The following is a list of Professors in the Medical Faculty:—Medicine, A. T. Houghton Waters, M.D., F.R.C.P.; Surgery, Rushton Parker, B.S., F.R.C.S.; Anatomy, W. Mitchell; Physiology, Richard Caton, M.D., M.R.C.P.

Public Pensions for the Victims of Scientific Labour.

THE President of the Pensions Commission of the French Government has addressed to the Paris Academy of Medicine a letter asking for a statement of the names of the *savants* who, within the last two or three decennial periods, have either lost their lives or been seriously injured in their scientific researches. A sub-committee of the Academy was thereupon named to draw up the required statement.

Anti-Vivisection Legal Absurdities.

AN able letter on the inconsistency of Anti-Vivisectionists, appears in the *National Reformer*. We make an extract:—"A year or two ago some men were charged with skinning frogs alive, and then putting salt on them to see which frog could be made to jump the farthest. As this was done for sport, and for a wager, the magistrate had to dismiss the case, remarking that had such actions been done for any scientific purpose a severe penalty could have been inflicted."

IN 1880, 26,588 inquests were held in England, against 27,053 in the previous year, at an expense of £86,842 13s. 5d., being an average of £3 5s. 3d. each.

A Family of "Quacks."

SHERIFF SMITH, of Greenock, has recently given a decision refusing an interdict of Dr. Levenson, of Glasgow, against S. A. Levenson, Arcade, Greenock, to have the defender interdicted from calling himself his (pursuer's) son:—The pursuer, the Sheriff says, is the son of a man named Jacobs or Levenson, who long carried on a quack business in Glasgow under the name of Dr. Levenson. The defender is the grandson of the old man and the nephew of the pursuer. Defender's father was commonly known there as Dr. Levenson. Probably neither of these two—certainly not the brother—ever received from any duly constituted authority the right to call himself Doctor. The pursuer, however, secured a medical degree from the University of Glasgow in 1859, and he has for the greater part of the time that has elapsed since been duly entered in the Medical Register; not, however, for the whole time. He was removed from the Register some years ago for reasons which have not been made very clear by him, and he says that he was restored to the Register after an interval of three or four years. But in the month of May last his name was again deleted from the register, and he states that the ground of the deletion was alleged unprofessional conduct on his part. The evidence led by the pursuer himself leaves no room to doubt either the cause of the pursuer's removal from the Register or the propriety of it. So that of the three *soi-disants* Drs. Levenson, who have been widely known to the inhabitants of Glasgow off and on for the last thirty or forty years, two never had any University title to the appellation of doctor, while the third received such a title, and has since been found by the proper authority to be unworthy of it, and has been deprived of the privileges which would otherwise have attended it. A good deal of time was taken up in an attempt to show that the pursuer's application was one in the success of which the public interests are concerned. The true interest of the public is, perhaps, that the whole family and all their concerns should be buried in a speedy oblivion. Neither the public at large nor the medical profession will elect the pursuer as their champion. *Non tali auxilio nec defensoribus istis*. Practically, the pursuer wants the Court to give him a monopoly in the production of the literary poison. His own contributions to the pestilent rubbish with which the Court has had to deal are indeed more disgraceful than the defender's. They are nastier in themselves, and they are given to the world as the compositions of a man who has had the advantages of a University training—advantages which he has prostituted to the lust of gain.

An Anti-Vaccination Demonstration at Dewsbury.

THE anti-vaccinationists at Dewsbury recently organised a demonstration against the vaccination officer, Mr. J. T. Marriott, of Batley. Two brass bands, torch bearers, sensational pictures, and an effigy of the obnoxious official took part in the demonstration. Mr. Marriott was one of the most amused of the spectators.

The Ethics of Homœopathy.

ON this subject a contemporary says practically the only part of homœopathy which now survives is the name, and that this seems to be retained, except by a very few practitioners, for "purposes of trade"—that is, to catch the patronage of people who have a *penchant* to be treated, as they say, "on principle." We are perfectly and literally warranted in saying this. The two essential peculiarities of Hahnemann's doctrine—the law of similars and the administration of infinitesimals—have been publicly disclaimed officially in our own columns by the Vice-President of the Homœopathic Society. Why, then, retain the "homœopathic label? Why, for the purposes of trade? For the exclusion of homœopaths from consultation and other courtesies, we cannot blame anybody but homœopaths themselves, who in retaining the name either do so because they believe in the homœopathic doctrines, or because they think it will pay to profess to do so.

Reductio ad Absurdum.

AT the Paris Société de Biologie M. Dumontpallier has recently made a series of communications on metalloscopy and cognate practices which go far beyond anything hitherto published on the subject. He asserts that one of the patients in his service, when hypnotised and prepared for experiment by the application of a silver brass plate on the left side of the forehead, can be made to contract certain muscles by the operator simply looking at them. In order to show that the contraction is really due to what he terms ocular influx (a form, no doubt, of the lately resuscitated neuric force), a pane of glass is interposed between experimenter and subject, and instead of looking directly at the muscle its image is stared at in a mirror. The ocular influx thus passes through the glass and is reflected by the mirror to the muscle, which immediately enters into contraction. If a drop of water be allowed to fall upon the gastrocnemius of this patient, it at once contracts, and a second drop produces its resolution. Finally, and marvellous to relate, if, when the patient is awakening from the hypnotic sleep, M. Dumontpallier should look at the region of the left third frontal circumvolution, or should point at it with his finger, she becomes aphasic; a second look or gesture restoring speech. A glance at the ascending frontal causes a movement in the arm, and so on.

Fever in the Flower-Pot.

TO the student of social and domestic meteorology the occurrence of atmospheric perturbations in tea-cups is a phenomenon by no means unknown. Nay, even, to quote the language of ordinary weather predictions, on occasions, no doubt rare, yet on occasions such perturbations do develop very considerable degrees of energy, and all are, more or less, dangerous to "vessels," be they "weaker" or stronger that come within their vortex.

But cyclones such as these are not the only sources of danger that beset drawing-room gatherings. It is quite dreadful to think that the atmosphere of a hot room in which plants are kept has been found to be impregnated with a moist vapour arising from the earth in which these are potted, and that "a sort of low fever *might* be generated in this way. And not only *might* be generated,

but, according to high authority, actually has been so. Fortunately, however, for the fair dames of London, only one instance, and that instance in Russia, has happened in which theory on the subject emanated in 1879 is believed to have in 1881 received confirmation. If, therefore, the angelic portion of the population throughout Europe be reckoned, the individual chances of attack by "a sort of low fever," due to drawing-room malaria from the cause named, are decidedly small.

Bequests and Donations.

MISS SUSAN BROWN, of Weston-super-Mare, bequeathed £500 to the Earlswood Asylum for Idiots, and £300 each to the Taunton and Somerset Hospital, the Weston-super-Mare Hospital and Dispensary, and the West of England Sanatorium. Mrs. Susan Crozier, of Clifton Road, Brighton, bequeathed £300 each to the Sussex County Hospital, and the Brighton Hospital for Sick Children. Mr. William Ward, of the Lawn, Brixton, bequeathed £100 each to the Royal Hospital for Incurables, and the Royal Hospital for Diseases of the Chest. Mrs. Caroline Collier, of Montpellier Square, Brompton, bequeathed £100 to the St. James's Dispensary. The Mercer's Company have given one hundred guineas towards the proposed Scarlet Fever Convalescent Home. The will and codicil of Dr. Archibald Billing, of 34 Park Lane, who died on September 2nd last have been proved by the executors, the value of the personal estate exceeding £45,500. The testator bequeaths to his wife all the cash in house and at bankers, and his furniture, plate, pictures, household effects, horses and carriages; and to his executor £100. The residue of his real and personal estate is to be held upon trust for his wife for life; at her decease a sum of consols is to be set aside to pay £100 per annum unto his daughter Florence until her marriage, upon the happening of which event the said consols are given to three granddaughters; and the ultimate residue is to be divided between his four daughters.

Hospitals in Paris.

THE Municipal Council of Paris has passed a resolution, by forty-eight votes against five, in favour of the entire secularisation of the public hospitals of that city. By the terms of the same vote, the credits asked for by the administration for the salaries of the almoners attached to the hospitals have been refused, at the same time, the Council increased the sum set aside for public instruction by 3,500,000 francs.

Resection of Small Intestines.

KÆBERLI has reported to the French Academy cases of resection of the small intestine, and advocates this operation. *The Chicago Medical Journal* says that the operation was successfully performed at Manassas Junction, during the war.

THE British Dairy Farmers have resolved in consequence of the large demand for goats, owing to the increasing popularity of goat's milk as a food for infants, to form a Goat Supply Company for the importation, breeding and supply of goats. The matter has been submitted to a committee of the Society to carry out.

The Vacant Professorship of Anatomy in the Irish College of Surgeons.

THE election to this important Professorship will take place on the 26th inst. The list of candidates which we gave in a recent issue has been considerably increased, and there are at present the following seven competitors:—Dr. Knott, Demonstrator of Anatomy in the School of the College; Mr. Ledwich, Lecturer in Anatomy in the School which bears his name; Dr. Charles, and Dr. Reid, both of them at present engaged in the teaching of anatomy in St. Thomas's Hospital School; Dr. Anderson, the chief assistant of Dr. Redfern in the Anatomical School of Belfast; and lastly, Dr. Cunningham, well-known as an Anatomical Teacher in the University of Edinburgh.

With seven candidates of such high quality and attainments before them, the Council can have no difficulty in selecting a professor who will do credit to the College, and confer great benefit on the school.

Presentation to Dr. W. G. Smith.

THE past and present students and staff of the Adelaide Hospital, Dublin, have presented Dr. W. G. Smith with a handsome clock, and an illuminated address, as a token of esteem and regard, on the occasion of his severing his connection as Physician and Pathologist to the hospital after a term of 15 years, to take up the duties of Regius Professor of Materia Medica in the University of Dublin; and Physician to Sir Patrick Dun's Hospital; to which he has recently been elected.

M. H. TOUSSAINT, in a paper read before the Academy of Sciences, supports the contagious character of tubercular disease.

DR. HEPBURN, Surgeon to the Meath Hospital, Dublin, has been appointed Visiting-Surgeon to the Brabazon Convalescent Home at Bray, co. Dublin.

By the contribution of £1,000 Mr. Sandhach has raised the endowment fund of the Roscoe chair at University College, Liverpool, to £8,836 towards the £10,000 required.

A CURIOUS statement is made in the *Bulletin de la Société d'Horticulture d'Orléans*, that the castor oil plant is an excellent remedy against flies. Those that alight on the leaves and suck the sap are said to fall down dead, their bodies becoming white. The castor oil plant is easily grown, and the experiment is worth a trial.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their population were—Bristol 16, Norwich 17, Plymouth 20, Brighton 21, Sheffield 22, Sunderland 22, Leeds 23, Hull 23, Birmingham 25, Wolverhampton 26, Bradford 26, Salford 27, Oldham 27, Newcastle-on-Tyne 27, London 28, Portsmouth 28, Manchester 29, Leicester 30, Liverpool 31, and Nottingham 32.

DR. ALFRED CARPENTER in a letter to the *Times* newspaper, of Saturday last, puts the water supply question upon a very practical basis. He suggests that it should be reduced to the same level of ordinary contracts; if the water companies give an insufficient or impure supply, they should be prosecuted by consumers in the same way as dishonest tradesmen. This is a devoutly to be wished for consummation, and we see no reason why a test case should not be brought about by a guarantee fund.

DR. R. P. P. TAAFFE, one of the physicians to the Royal Alexandra Hospital for Sick Children, Brighton, has been presented with a testimonial, marking the appreciation of that gentleman's services on behalf of the hospital, of which he is also one of the founders. The testimonial, which took the form of a very handsome watch and chain with a suitable inscription and a cheque for £220, was presented to the recipient by the Mayor of Brighton.

WE are asked to announce that Prince Leopold (Duke of Albany) has become the Patron of Chelsea Hospital for Women, King's Road, and the Princess Frederica of Hanover, the Duchess of Cambridge, and the Princess Mary of Teck, have given permission for their names to be added to the Patronesses of the Hospital. The Queen, Princess of Wales, the Princess Christian, and their Royal Highnesses named above, have each accepted a portrait album specially designed to commemorate "Ye Old English Fayre" which was organised for the benefit of the charity.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 36, Bombay 25, Paris 28, Geneva 22, Brussels 18, Copenhagen 20, Stockholm 23, Christiania 28, St. Petersburg 43, Berlin 24, Hamburg (State) 23, Dresden 21, Breslau 28, Munich 31, Vienna 30, Prague 32, Buda-Pesth 38, Naples 28, Turin 24, Venice 25, Alexandria 31, New York 30, Brooklyn 24, Philadelphia 21, Baltimore 25. No returns were received from Amsterdam, Rotterdam, The Hague, Rome, Madras, and Lisbon.

THE mortality last week in the large towns from diseases of a zymotic class per 1,000 of the population were:—From scarlet fever 8.1 in Hull, 5.0 in Nottingham, and 2.2 in Sunderland; from whooping-cough, 4.1 in Salford, and 1.6 in Birmingham; from measles, 2.9 in Leeds, and 2.1 in Liverpool; and from "fever" (principally enteric), 1.4 in Oldham. In Hull 24 more fatal cases of scarlet fever were recorded, raising the number registered within this borough since the beginning of July to 642. The 42 deaths from diphtheria in the twenty towns included 18 in London, 13 in Portsmouth, 3 in Manchester, and 2 both in Birmingham and Liverpool; the annual death-rate from this disease in Portsmouth averaged 3.1 per 1,000 during the last quarter of 1881. Small-pox caused 37 more deaths last week in London and its suburban districts, and 2 in Salford; no fatal case was returned in any of the other large towns.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

EDINBURGH ROYAL INFIRMARY.—The general meeting of the subscribers to the Edinburgh Royal Infirmary was held in the Council Chamber on the 2nd inst., the Lord Provost presiding. The report submitted by Mr. Trainer is interesting in the highest degree as pointing out the unwieldy proportions to which hospitals in Scotland, as well as elsewhere, have attained, and the correspondingly increased difficulty of maintaining them, as pointed out in our Scotch "retrospect" for the past year. The following are the more material portions of the report:—Patients remaining in the Hospital at 1st October, 1880, 458; patients admitted between 1st October, 1880, and 1st October, 1881, 5,288—total, 5,746. Of these there were—Dismissed cured, 2,801; ditto relieved, 1,651; ditto on other grounds, 325; died in hospital, 475—total, 5,252; patients remaining at 1st October, 1881, 494. Of the cases brought to a termination during the year, 480 were cases of infectious disease treated in the fever house in the old Infirmary, including 169 cases of scarlet fever; 2,113 were ordinary medical cases, and 2,659 were surgical cases. The number of children in the hospital during the year has averaged from 30 to 40, the great majority of whom were treated in the surgical wards. The daily average number of patients in the hospital during the year was 520. There were also 1,500 out-patients during the year. There have been received during the past year:—Legacies and donations of £100 and upwards for the Infirmary, £6,572 8s. 7d.: which were applied to meet the excess of ordinary expenditure for Infirmary, including Fever Hospital (£31,720 16s. 8d.) beyond ordinary receipts (£21,902 14s. 4d.), £9,818 2s. 4d., leaving a deficiency of £3,245 18s. 9d. The ordinary income for the year now reported on—£21,902 14s. 4d., as compared with £21,540 14s. 2d., for the preceding year—shows an increase, notwithstanding the great depression which has existed during the year, of £362 0s. 2d. The students' fees amounted to £3,443 12s., and for the year ended 1st October, 1880, they were £4,179 8s., and in the previous year, £2,643 13s.

GLASGOW HEALTH LECTURES.—These lectures, delivered under the "Combe Trust," are now published together. With the exception of the lecture by Dr. Yellowless, they form a volume by no means creditable to the intelligence or culture of the medical profession in Glasgow. Of Dr. W. L. Reid's, published under the auspices of the "Christian Women's Association," addressed "only to women," and consequently bought chiefly by young men, we have already spoken. Dr. Gairdner's was characterised by his usual nebulosity and irrelevancy, and the faculty of giving groundless offence. These are opinions entertained largely by the profession in Glasgow; but the luxury of expressing opinions is one not much indulged in. We understand a fee of £10 10s. was paid to each lecturer, and thus an excellent advertisement was duly provided.

ALCOHOLIC CONVULSIONS.—In the course of the recent trial at Glasgow, commented upon in this number, the question arose as to a difference between "alcoholic fits" and "epileptic convulsions," and Dr. Robertson is reported to have said, "I know such things as alcoholic fits. They closely resemble, and might be taken by a non-medical person for epileptic fits." We have been hitherto under the impression that inordinate indulgence in alcohol might primarily induce epilepsy; we have seen the fits thus occa-

sioned, and have been completely unable to distinguish their phenomena from those of genuine epilepsy. We shall be very pleased if Dr. Robertson will favour us with fuller details as to his views on this important matter.

THE NATURAL HISTORY CHAIR IN EDINBURGH.—It is reported that Lord Rosebery, on behalf of the Crown, has offered the Chair of Natural History in the University of Edinburgh to Dr. F. M. Balfour, the eminent embryologist, and Secretary to the British Association. It is uncertain whether Dr. Balfour, who is at present in Madeira, will accept the offer.

GLASGOW ROYAL INFIRMARY APPOINTMENT.—Dr. James Alexander Adams has been appointed extra Surgeon to the Glasgow Royal Infirmary Dispensary. We congratulate the directors on the appointment.

CALICO BALL.—A "calico ball" is to be given in Glasgow in March, the proceeds of which are to be given in aid of the Glasgow Royal and Western Infirmaries.

HEALTH OF HELENSBURGH.—Dr. Henderson's "Endemic Influenza" does not seem to have made a lasting impression on the death-rate of Helensburgh, for, from the mortality returns just published, it would seem that "the Brighton of the west" has both a fair share of health and salubrity. In the course of the last year 150 deaths were registered, equivalent to an annual mortality of only 14 per 1,000 of the population, many of the deaths being those of persons over 70 years of age. The death-rate per annum of some of the English towns is 32. Of 270 births registered during the year only 1 was illegitimate. There was no "revival" in Helensburgh during the year.

THE PROFESSORSHIPS OF PRACTICAL ANATOMY IN THE IRISH COLLEGE OF SURGEONS.—In addition to the candidates for this chair, mentioned in our last impression, we are informed that Dr. William Allen, Senior Demonstrator of Anatomy in the University of Glasgow, also aspires to the office. Dr. Allen is a graduate of Queen's University, Ireland, and a gold medallist. He is author of "The Varieties of the Atlas and Morphology of its Transverse Process" (Jour. Anat. and Phys.) "On Tertiary Occipital Condyle" (Ibid.) And "On the Anatomical Changes Induced at the Elbow by Luxation Backwards of the Head of the Radius in Early Life" (Glas. Med. Jour.) By all who knew him, Dr. Allen is held in high esteem for his ability and enthusiasm in his work, and the modesty of his disposition. His claims to the chair are of high order, and should they carry such weight as to prefer him to the office the University of Glasgow will lose a great favourite.

THE CONVICT FERGUSON.—There is at present lying in the prison of Glasgow, a man under sentence of death. Efforts, and we think humane and highly proper efforts, are being made to save his life, for the following very weighty reasons. The culprit was at one time unquestionably insane. He was admitted into Gartnavel Asylum in 1874, and his distinct insanity at that time was testified to at the trial by such a competent authority as Dr. Blair. He was subject, it was brought out at the trial to "convulsion fits," "during which he had to be held down, and on one occasion he bit his tongue." Dr. Robertson, of the City Parochial Asylum, an admitted authority on the subject of insanity, and a highly educated and judicious physician, signed the medical certificate on which Ferguson was admitted into Gartnavel; while at the trial he expressed the opinion that the insanity was due to intemperance, and of a temporary nature, he admitted that the symptoms of insanity then exhibited were "not the most characteristic symptoms of *delirium tremens*." Dr. G. R. Mather considered the prisoner at the same period "a dan-

gerous lunatic," and that the symptoms referred to were "characteristic of insanity as distinguished from *delirium tremens*." The insanity of this unfortunate man is further testified to by Dr. David Walker, Dr. Beaton, and Dr. Thomas Johnson, all gentlemen to whose opinion deference is due. In passing sentence of death Lord Deas said, "Apart from the fact that you are a weak-minded person—partly from the habit of drinking, and partly it may be from some other causes, &c. . . . the Crown will be aware of the fact that I suggested that more lenient verdict (manslaughter) to the jury." The prisoner's conduct during the trial was hardly that of a sane man. Altogether this is a case in which the exercise of the clemency of the Crown seems imperative. With legal technicalities and duties we do not profess to be conversant, but we consider the frequent conflict between the legal and medical professions as to what constitutes insanity, an unfortunate one; and apart entirely from promptings of humanity, it is but reasonable to believe that medical men are better judges of the factors of an unsound mind than the highest lawyers in the land. The following episode in this trial, as reported in the papers, strikes us strangely:—"Lord Deas—Have you any doubt that the prisoner was capable of knowing that murder was contrary to the law of the land? Witness, (Dr. Sutherland) I have no doubt. Lord Deas—I should think not." What inference would the jury draw from this, before the medical men for the defence were examined? It by no means follows that there is no recovery from insanity, but in the case of Ferguson, there are the strongest grounds for doubting his sanity when he murdered his unfortunate wife. If ever then, there was a case for the exercise of the clemency of the Crown, this is one, and we trust that the moral sense of a large city, profuse in its professions of Christianity, will not be shocked by the execution of such an one. We must remember that the bones of the murdered Docherty, and his heart-broken father, to whom death, at least, extended compassion, still proclaim from the grave that the upward of humanity is not through blood retribution, but through education and loving kindness.

PROFESSIONAL ADVERTISING.—The following advertisement has been appearing for some weeks in the *Huntly* (Aberdeenshire) *Express*:—

"JAMES DOW SAINTER.
CONSULTING SURGEON.

F.R.C.S., EDINBURGH; M.R.C.S., ENGLAND; L.R.C.P.,
LONDON; and L.S.A., LONDON.

Address—No 1 Duke Street, Huntly.

Hours—10 a.m. to 4 p.m. daily."

Mr. James Dow Sainter evidently wants looking after by the gentlemen who proposed him "as a fit and proper person" for the "Fellowship Distinction" of the Edinburgh College of Surgeons.

ILLNESS OF SIR ROBERT CHRISTISON.—We regret to learn that this venerable and distinguished member of the profession is so seriously ill that only a few of his most intimate friends are allowed to see him. Professor MacLagen is in attendance on Sir Robert.

MIDWIFERY FOR MIDWIVES. (a)

WHEREVER women are permitted by the State to undertake the duties of an obstetrician, in however restricted a sense, there ought to be no necessity for impressing the urgent necessity that such attendants should possess at least a rudimentary acquaintance with the science and art of midwifery; and yet how few even of "certificated"

(a) "Midwifery for Midwives." Translated from the German by J. E. Burton, L.R.C.P. Lond. Churchills. 1880.

midwives in this country can lay any real claim to be considered more than fortunate empiricists in respect to the cases they attend? And this, it must be urged, is in great part due to the lack of manuals for the instruction of women intending to become midwives.

Although Dr. Fancourt Barnes' "Handbook for Midwives," published about 1879, is useful and trustworthy, it contains too little of the actual knowledge required; but the "Official Handbook of Midwifery for Prussian Midwives," of which Mr. Burton has rendered a most excellent English translation, leaves nothing to be desired in this respect. It describes all connected with the physiology, anatomy, and complications of labour, and gives such directions as will enable an intelligent woman to acquit herself with credit under even difficult circumstances; and it further insists on skilled professional aid being at once summoned in every case of anticipated danger. For students and practitioners, moreover, the work will be useful as showing the extent to which a well-educated midwife may be trusted, and also it may be in explaining the smaller details of treatment of children, which Englishmen as yet are but little skilled in. Mr. Burton has done his part of the labour with signal success, and we trust the time may not be far distant when the State will demand an acquaintance with the contents of this little manual from every candidate for a certificate to practise as a midwife.

Correspondence.

THE HARVEIAN LECTURES ON MENSTRUATION AND ITS DERANGEMENTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As my Harveian lecture will shortly be published in a separate form, with some additions, in which the mechanical views of Dr. Graily Hewitt will be more fully considered than I had time for in these lectures; and as, moreover, the abstract from which he quotes as having appeared in your journal was not written by, or known to me, I trust he will not consider me wanting in respect or courtesy if I decline at present to reply to his letter or enter into controversy until the full text appears, when I shall have much pleasure in accepting any challenge he may offer either as regards the anatomy, physiology, pathology, or therapeutics which I have brought forward in these lectures.

I would, however, beg permission to make one remark, viz., that I accept Dr. Graily Hewitt as quite as good an authority as Klob, Thomas, or any other he may quote, so that he need not trouble himself by any reference to them, for the matter between us is not to be settled by any quotation of names either for or against—it is a question of anatomical and physiological fact; not a matter of opinion; least of all imagination. I am quite prepared and anxious to discuss it with Dr. Graily Hewitt in your columns or elsewhere, alone, or in company, as he may prefer. But so far as I presumably am concerned, no amount of names that he may bring forward, will weigh one atom with me more than his own, if as much, on this question, which I regard as specially his.

Your obedient servant,

ALFRED MEADOWS.

George Street, Hanover Square.

NOTES ON VACCINATION AND RE-VACCINATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am much obliged to Dr. Sharpey for his kind criticism of my paper on the above subject in your journal of the 2nd November last.

I did not try Bryce's test in any of those cases reported, I used the term "successful" to those cases which had a well marked vesicle resembling very closely the vesicle of primary vaccination.

To all intents and purposes these were successful cases of re-vaccination, whether we call them true pocks or spurious pocks, for no other pock could be produced in the previously vaccinated subject. I had one or two examples of vesicles that could not have been distinguished from the vesicles of primary vaccination by the naked eye, and these appeared

to run the usual course, but I cannot speak to the subsequent pitting, characteristic of the primary cicatrix, probably I should find this absent.

I suppose a true Hunterian chancre is never seen *twice* at different periods, and in the same subject.

Yours truly,

WILLIAM BERRY, M.R.C.S. Eng.

Wigan, Jan. 6, 1882.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

DR. THORWOOD will please receive our best thanks.

DR. HAYWARD.—We hope to refer to the subject in our next.

DR. M. S.—The objection is a very narrow-minded one, and unworthy an educated man.

AN INQUIRER.—The substance referred to has not come under our notice; we will make inquiries and report results.

AN EDINBURGH STUDENT should write to the Editor of the *Students' Journal*, who will doubtless satisfy his curiosity.

DR. ADAMS.—It is not the first time the same distinguished physician has opposed himself to the weight of professional opinion. The result, however, shows that whatever influence he may have exerted in the past his voice counts for little now.

PUZZLED.—The case is a simple one; urticaria.

G. A. B.—When the article first appeared there were only three in London. Since that time, however, several others have made their appearance, and soon we may expect they will be commonly found in all institutions where they can be turned to good account.

JAOK.—It is only with great difficulty we have been able to arrive at your real meaning. Your caution is wholly uncalled for; no one is likely to be interested in your proceedings, and we can offer you no prospects of a position such as you so modestly declare your competency to fill.

L'ESTOMAC.—They have been translated by Dr. Saundby, of Birmingham.

AN ASPIRANT.—Your "first attempt" at versification is not particularly successful. We are sorry to discourage you, but you are evidently not "a horn poet;" students will certainly stand a better chance of remembering these dry details with the usual vehicles at their disposal than with the use of disjointed and non-rhythmical lines.

A LADY STUDENT may rely on our willingness to do all in our power to assist the attempt she is engaged in. The letter shall be forwarded.

DR. HAYES.—An amended Scale of Medicines and Medical Stores for Merchant Ships, dated November, 1881, has just been issued by the Board of Trade, which is intended to supersede the Scale hitherto in force. You can get it by application in the regular way.

FARMAR AND SEALEY FUND.

To the Editor of the *MEDICAL PRESS AND CIRCULAR*.

SIR,—With reference to my letter which you kindly inserted in the *Medical Press and Circular* of October 19th last, in which I mentioned the fact of a subscription being in progress for a testimonial to Corporal Farmar, V.C., and Private Sealey, of the Army Hospital Corps, for their gallant conduct at the disaster of Majuba Hill, and gave a short account of the wounds by which they had been disabled for further military service, I have now the pleasure to state that £170 have been subscribed, and that this amount, equally divided, has been presented to the two men by the Director-General of the Army Medical Department. The sum named includes a generous donation of twenty-five guineas from the family of the late Surgeon London, A.M.D., under whose directions Corporal Farmar and Private Sealey were carrying on their duties at the time that lamented young medical officer received his mortal wound. The presentation has been notified by a circular from the Director-General to the officers and men of the Army Medical Department.

I am, Sir, your obedient servant.

THOS. LONGMORE, S.G.I., H.P.,

Professor of Military Surgery.

Netley, Jan. 8, 1882.

A MEMBER OF CONGRESS.—The volumes have been issued during the last few days. The Hon. Sec., Sir Wm. MacCormac, will doubtless supply you with the information you need.

PROFESSOR MARSHALL, F.R.S., will deliver a lecture at the Brompton Consumption Hospital on Monday next, at 3 p.m. "On Diseases of the Chest-walls requiring Surgical Treatment." Members of the profession will be admitted thereto on presentation of card.

ST. JOHN AMBULANCE ASSOCIATION.

To the Editor of the *MEDICAL PRESS AND CIRCULAR*.

SIR,—I am requested by the Central Executive Committee of the St. John Ambulance Association to acquaint you, and through you the profession, that a meeting of representatives from the different

London hospitals, the medical staff of this Association, and of divisional police surgeons will be held at the offices of the Association, St. John's Gate, Clerkenwell, on the afternoon of Monday, the 16th of January, at half-past four o'clock, to consider a system of placing ambulance stations in telegraphic communication with the hospitals of the metropolis, and the best means of wheeled transport.

I have the honour to be, Sir,

Your obedient servant,

EDMUND A. H. LECHMERE, Chairman.

MR. MURRAY (Edinburgh).—We fully appreciate the difficulties with which students have to contend, but fear our columns are hardly suitable for the insertion of the papers suggested. However, if you will send us a specimen we will consider the matter and advise you.

DR. PANTALEONI (Rome).—It will afford us much pleasure to accede to your request.

R. S. M.—We have purposely avoided expressing an opinion while the case is *sub judice*.

MEETINGS OF THE SOCIETIES.

THE OBSTETRICAL SOCIETY OF EDINBURGH.—This (Wednesday) evening, at 8 o'clock, Prof. Simpson, "Case of Basilia."—Dr. Murray, "Cases of Complicated Labour."—Dr. W. J. Kennedy, "Case of Pregnancy at the age of 62."

THE ROYAL INSTITUTION.—Tuesday, Jan. 17, at 3 p.m., Prof. J. G. McKendrick, "On the Mechanism of the Senses."

Vacancies.

Cumberland Asylum.—Assistant Medical Superintendent. Salary, £100, with board. Applications to Dr. Campbell, The Asylum, Garlands, Carlisle.

Drogheda Union, Duleek Dispensary.—Medical Officer. Salary, £110, and £20 as Medical Officer of Health. Election, Jan. 23.

Huddersfield Infirmary.—Senior and Junior House Surgeons. Salaries, £20 and £40 respectively, with board. Applications to the Hon. Sec. before Jan. 21.

Lincoln County Hospital.—House Surgeon. Salary, £100, with board. Applications to the Secretary before Jan. 16, of whom also further particulars can be obtained.

Monmouth Union.—District Medical Officer. Salary, £40, with the usual extra fees. Applications to the Clerk at the Union Office, Monmouth, Wales, by Jan. 18.

Royal Surrey County Hospital.—House Surgeon. Salary, £75, with board. Applications to the Secretary, Town Hall, Guildford, before Jan. 30.

St. Asaph Union.—Medical Officer for the Llanfairvalhalarn District. Salary, £88, with the usual extras. Applications to the Clerk, Union Offices, St. Asaph, Flintshire, by Jan. 20.

St. Marylebone General Dispensary.—Obstetric Physician. Honorary. Also a House Surgeon. Salary, 100 guineas per annum. Applications to the Secretary by Jan. 16.

Sussex County Lunatic Asylum, Hayward's Heath.—Junior Assistant Medical Officer. Salary, £100, with board. Applications to the Medical Superintendent by Jan. 18.

Appointments.

BERNAYS, H. L., M.R.C.S., Medical Officer of Health for Charlton.

BROWN, M. L., M.B., Assistant Medical Officer of the Male Department of the Middlesex County Lunatic Asylum, Colney Hatch.

CURRIE, J., M.D. Glas., L.R.C.S. Ed., Medical Officer for the Berry Pomeroy District of the Totes Union.

DALTON, C. G., M.R.C.S., Medical Officer for the Second and the Eleventh Districts of the Lincoln Union.

DAVIES, D. A., M.B. Lond., M.R.C.S., Physician to the Swansea Hospital.

DREWITT, F. G. D., M.B. Oxon., M.R.C.P. Lond., Assistant Physician to the Victoria Hospital for Sick Children.

FITZGERALD, G. H., M.D., Medical Officer to the Workhouse and District of Ponteland.

SHEPPARD, C. E., M.D. Lond., Resident Assistant Physician and Medical Registrar to St. Thomas's Hospital.

Births.

AVELING.—Jan. 6, at 14 Portland Place, Lower Clapton, the wife of Charles T. Aveling, M.D., of a son.

CROLY.—Jan. 1, at 7 Merrion Square North, Dublin, the wife of Surgeon Croly, F.R.C.S., of a son.

DOLAN.—Dec. 31, at Horton House, Halifax, the wife of T. M. Dolan, F.R.C.S. Ed., of a son.

HAYES.—Jan. 6, at 32 Merrion Square South, Dublin, the wife of Richard A. Hayes, M.D., of a son.

NESBITT.—Jan. 4, at 34 Cambridge Place, Hyde Park, London, the wife of Dawson Nesbitt, M.D., of a daughter.

Deaths.

BENTLEY.—Jan. 2, at 27 Moyné Road, Ranelagh, co. Dublin, Thomas H. Bentley, M.D. in his 74th year.

DASHWOOD.—Dec. 28, at Putney, J. Dashwood, M.R.C.S., formerly of Wellington Street, Southwark, aged 78.

GORE.—Jan. 2, at Tunbridge Wells, Henry John Gore, M.D., in his 85th year.

HAMILTON.—At Dundrum, co. Dublin, Wm. E. Hamilton M.D., late Medical Officer of Carney Dispensary, aged 83.

LODGE.—Dec. 24, at his residence, 33 Shaw Street, Liverpool, Robert T. Lodge, M.D., aged 62.

FRATER.—Jan. 2, at 90 Malson Dieu Road, Dover, Augustus Frater, M.D., late of Woolwich, aged 70.

SWYER.—Dec. 31, at 25 Mile End Road, E. E. Swyer, M.D., aged 59.

TURNER.—Jan. 8, at Aahurat, Clapham Common, Roger Turner, M.D., late of Petworth, Essex, aged 76.

CLINICAL LECTURE

ON

IMPERFECT INVOLUTION OF THE UTERUS AND ITS CONSEQUENCES.

By LOMBE ATHILL, M.D., F.R.C.P.,
Master of the Rotunda Hospital, Dublin.

SUBINVOLUTION of the uterus is the primary cause of very many of the ailments from which women suffer. In the first instance, it is frequently the cause of profuse menstruation; that this should be so is easily understood, for not only is the quantity of blood supplied to the uterus unduly great when this condition exists, but also the mucous membrane lining its cavity frequently becomes unhealthy; then it is the most common of all the causes that produce retroflexion of the uterus, and, at a later date, it predisposes to, if it be not the actual cause of, chronic metritis and hypertrophy of the uterus, while it markedly favours the occurrence of granular erosion of the cervix and of endometritis. I must, therefore, dwell at some length on so important a subject.

When we speak of subinvolution of the uterus, we mean that the process by which the womb regains its original size subsequent to delivery, or abortion, has been from some cause retarded or arrested; this process has been termed involution, and when it is incomplete we talk of the uterus as being in a condition of imperfect involution, or more commonly, of subinvolution.

The involution of the uterus should be completed within a few weeks after the date of delivery. It is one of the most remarkable phenomena which occur in the human body. The uterus, immediately before the expulsion of the fœtus, measures about fourteen inches in length, and weighs twenty-five ounces, often, indeed, even more. Immediately after, its size is diminished to considerably less than one-half its former bulk, its weight being propor-

tionally reduced; while, if the process proceed regularly and unchecked by any cause, the womb will, after the lapse of five or six weeks, be less than three inches in length, and weigh but two ounces. The first step in this process is, that the supply of blood to the uterus is checked, and the circulation of blood through that organ interrupted, by the contraction of the muscular fibres of the uterus, a process which commences the moment labour terminates, and goes on in a more or less painless manner for some days subsequently; while, at the same time fatty degeneration and disintegration of tissue, on the one hand, and absorption on the other, rapidly complete the work of reducing the uterus to its normal size, and restoring its compactness of tissue.

But you can easily understand that numerous causes may interrupt this process; thus, in weakly, debilitated women, the uterine contractions may not be sufficiently powerful to check the blood supply, consequently the nutrition of the organ may continue almost as active as previous to delivery, and accordingly the uterus will remain in a state which may be considered as one of permanent congestion terminating in hypertrophy. Instances of this are very numerous. A similar result may follow in a healthy muscular woman if she leave the recumbent posture too soon after delivery, and, as many of the lower orders do, return to her ordinary occupations, long before the uterus has regained its normal size. Again, pelvic inflammation in any of its varieties is a common cause, interrupting and often arresting the involution of the uterus. Subinvolution may follow on abortion, even when it occurs in the early months of pregnancy, a fact you should not overlook; indeed, my experience leads me to think it is more likely to occur after abortion than after labour at the full term.

The reason why this should be so is easily understood. At the termination of the full term of gestation the uterus is prepared to undergo a process of fatty degeneration and absorption; in fact, this process seems in some cases to commence concurrently with, if not actually prior to, the first symptoms of labour, and it is the natural termination to parturition, the growth of the organ having ceased some time previously, but in cases of abortion not only is the

uterus not prepared for the process by which the increase in its size is reduced, but it is called in to undergo this reduction while in a state of rapid growth. The ovum being expelled the growth of the uterus always ceases, but very frequently no attempt is made by Nature to reduce the size of the organ, and this is specially marked when a woman has aborted several times in succession.

The principles which should guide you in the treatment of subinvolution of the uterus are alike in all cases, but the actual method you will follow, and the agents you will employ in carrying out these principles, will necessarily vary in each case. As it is recent, or of long standing, complicated by the existence of congestion, of inflammation, or of hypertrophy of the uterus, its appendages or the neighbouring viscera, or by the presence of granular erosion, retroflexion of the fundus, &c.

Subinvolution of the uterus is of such common occurrence, and is met with under such varied conditions, both as regards duration, complication, and symptoms, that it would be impossible for me to enumerate all the phases it presents, or to mention all the points of interest connected with this condition, you must, by watching the cases under treatment in the wards of this hospital and in the out-patient department, endeavour to make yourself familiar with these, but you will find that all these may be roughly divided into three classes, each class being, in point of fact, a different stage of one and the same affection, it being of course understood that many cases will be met with holding a more or less intermediate position between one or other of these classes.

1st. We have those in which the affection is of recent date, menstruation being profuse, the uterus being soft and engorged, as well as large, the os and cervical canal being patulous, the vagina often being tender and inflamed.

2nd. Cases of longer standing, in which the extreme softness of the uterus no longer exists, though induration has not as yet occurred, there is generally copious uterine catarrh, with more or less erosion of the lips of the os uteri, menstruation being, as a rule, profuse.

3rd. Still more chronic cases, in which hypertrophy of the whole organ, and especially of the fundus, has taken place, with induration of the cervix, the fundus, which is frequently retroflexed, is tender to the touch, and sexual intercourse consequently often painful. Menstruation sometimes continues to be profuse, but very often, as time elapses, becomes scanty.

(1). The cases comprised in the first class—namely, those of recent origin, do not come under observation nearly so frequently as do the others. If women do not make a good recovery after parturition they generally think that their sufferings are due to mere debility, and that time will set them right; they may be nursing, though unfit to do so, and menstruation may not have as yet regularly recurred; the pain in the back, the copious leucorrhœa, and the inability to walk may not be deemed of sufficient importance to demand special treatment; but still, a considerable number of women do, from time to time, come under observation within two or three months after their confinements, in whom the uterus will be found to be enlarged, soft, and congested, the cervical canal patulous, and pouring out a copious muco-purulent discharge. The soft and heavy body is very liable to bend backward, and in time to become permanently retroflexed. In such cases the indications for treatment are clear. The distended blood-vessels of the uterus should be relieved by the abstraction of blood, its muscular fibres should be stimulated to contract by applications made to the interior of the uterus, and by the exhibition of ergot, strychnia, &c. The fundus, if retroflexed, should be supported and retained in as nearly as normal a position as possible by means of a pessary, and, at the same time, every effort should be made to invigorate the general health. It is in such cases as these that postural treatment, judiciously carried out, is often of so much value. Menstruation, if profuse, must be restrained, even if for that pur-

pose plugging the vagina becomes necessary. Should the woman be nursing she should be made to wean the child.

It is a very hazardous proceeding to apply leeches to the cervix in these recent cases; their application would almost certainly be followed by dangerous hæmorrhage, but blood should be extracted from the uterus at short intervals by puncturing the cervix with a sharp lancet-pointed knife, by which means the quantity taken can be regulated to the greatest nicety. When the cervix is very soft and congested puncturing has to be done with care, otherwise profuse bleeding may occur. The point of the knife should not, in the first instance, penetrate to a greater depth than about the 1-8th of an inch, if blood does not flow sufficiently freely another somewhat deeper puncture may be made. The quantity of blood taken at one time should be small—from half-an-ounce to an ounce is quite sufficient to relieve the local congestion; sometimes even a lesser quantity suffices, but the operation must be repeated at short intervals of two or three days. Should the bleeding be at all profuse it can at any moment be restrained by placing against the os uteri a small pledget of cotton to which a piece of string should be affixed, so that the patient can remove it herself after a few hours. By adopting this precaution you may feel perfectly sure that no undue loss of blood will occur; indeed, if the patient be seen in your own consulting rooms, or in the out-patient department of an hospital, it is generally wise to adopt this precaution before dismissing her.

Various agents are used for the purpose of stimulating the uterus to contract and of lessening the irritability of the intra-uterine mucous membrane, all of these must, to produce any satisfactory effect, be applied to the interior of the uterus, and, indeed, be carried up to the fundus; those most commonly employed are—(1) carbolic acid; (2) tincture of iodine; (3) iodine dissolved in carbolic acid (a preparation to which the name of iodised phenol has been given); (4) nitric acid; and (5) the solid nitrate of silver. I give them in the order in which I recommend their employment.

In recent cases of subinvolution I seldom employ any agent except carbolic acid, it is mild in its effects, seldom causes much pain, and, with care, is quite safe. Let me here give you one rule from which there should be no exception—namely, never apply carbolic acid or any other agent to the cavity of the uterus unless the os internum is sufficiently patulous to permit of the easy passage of the probe through it. If you neglect the observance of this rule you will certainly get into trouble. Carbolic acid, tincture of iodine, or the iodised phenol should be applied about every third or fourth day, and if much congestion be present the cervix can be punctured immediately upon the application being made. This will have the double effect of relieving pain should the carbolic acid have caused any, and by lessening the congestion facilitate the contraction of the muscular fibres of the uterus. Carbolic acid applied to the surface of the uterus makes a superficial slough; in fact, it blisters gently the intra-uterine surface. At the moment of application some pain is usually felt, but this rapidly dies away, and, indeed, it often relieves previously existing pain, specially when that is due to hyperæsthesia of the uterus. Nitric acid or the nitrate of silver are not suitable in recent cases.

I have already said that postural treatment is of much value in cases of subinvolution. By postural treatment, I mean the keeping the patient mainly in the recumbent position, and thus preventing the vessels of the uterus and its appendages from becoming unduly distended with blood. But this method can be carried too far. A patient should never be confined to bed, or even to a couch, for such a length of time as to injure her general health. Consequently, I advise you to allow your patients to take a moderate amount of exercise in the open air daily. Walking for a short time is probably the best kind of exercise she can have, but she must not stand about, and the moment the walk is over let her lie down; if she be unable to walk, or that it causes pain, driving in an

easy carriage or Bath-chair must be tried, in fact, the patient should lie almost constantly, except when taking exercise. But many patients cannot, or will not, lay up; you must then content yourself with pointing out how injurious standing or sitting upright for a length of time is, warning the patient at the same time that she will retard her recovery by so doing. As already mentioned, the fundus is frequently flexed in these cases; when this is so, a properly adapted pessary not only often relieves pain, but materially aid our other treatment.

(2.) The condition I have described being overlooked, or neglected, the affection passes into another stage. The uterus is no longer unduly soft, but feels firm to the touch, both the body and cervix being enlarged, and the fundus very frequently retroflected, pressure on any part of the organ with the finger causes pain; in fact, hyperæsthesia of the uterus exists, and this explains two symptoms, one or both of which are now commonly present—namely, the distress which walking so commonly causes, and the pain the patient often suffers during sexual intercourse. Menstruation still, in far the majority of cases, continues to be unduly profuse, while, on looking through the speculum, more or less extensive erosion of the lips of the os uteri will generally be observed. Copious uterine catarrh is also nearly always present.

Here, as in the former case, you have to direct your attention to the lessening of congestion and the reduction in size of the enlarged uterus, and to the relief of pain; but your task is now much more difficult, you will often find it hard to obtain sufficient blood by puncturing the cervix, though this generally can be effected by making the knife penetrate to a greater depth, the hot water vaginal douche sometimes acts exceedingly well in these cases, and its use should never be omitted. The application of carbolic acid, or better, the iodised phenol is still needed, and in some obstinate cases nitric acid should be employed. But none of these agents are to be used till the tenderness of the uterus is lessened, and any symptoms of inflammation which exist removed; in fact, you are now dealing with a state of chronic inflammation, the result of neglected subinvolution of the uterus. I must, however, defer till a future occasion entering into details of the treatment you should adopt under these altered circumstances.

(3.) The third class comprises those cases which have passed into a still more advanced stage. The walls of the uterus are thickened and hypertrophied, though the actual depth of the uterine cavity, as proved by the use of the sound, may be less than previously. The fundus and cervix are still generally tender to the touch; and if the body has been flexed in the early stage, the flexion is now incurable. Menstruation in the majority of cases, instead of being profuse, now appears in diminished quantities, though in a few the flow is still excessive. The patient nearly always complains that walking causes distress, and of a sense of fulness in the pelvis, and a distressing feeling as though the uterus were prolapsed. In fact, you have hypertrophy, with hyperæsthesia of the whole uterus, associated with which there is an unhealthy condition of the intra-uterine mucous membrane. The heavy uterus sinks low in the pelvis, and presses on the viscera, and its natural supports being now wanted, it receives a jar from every motion. Here you have to deal with one of the most troublesome and difficult forms of uterine diseases which it is possible to conceive, and one which will tax all the resources at your command to the utmost.

Local blood-letting now is of comparatively little value, but it may be tried. The action of carbolic acid is too feeble to produce much effect on the hardened uterus. Iodised phenol will do better; but even that agent, strong though it be, is generally insufficient. So, too, is even nitric acid. On the whole, I think in these cases that the solid nitrate of silver introduced into the cavity of the uterus is the most efficient agent. Still I employ it very seldom, and only have recourse to it in those cases in which, menstruation being profuse, the other agents I have mentioned have proved inefficient.

The free use of the thermo-cautery sometimes is of great use in these chronic cases. Pessaries, in general, seldom suit them. Often they cannot be borne. The one I have found most beneficial in relieving the distressing bearing-down sensation, is Salt's watch spring pessary. The chief objection to it is, that being covered with soft rubber, it is acted on by the vaginal secretions, and rapidly becomes coated with a deposit, and consequently must be removed at short intervals for the purpose of being cleansed.

The sufferings endured by patients whose cases have passed into the third stage I have just described are often great and, unfortunately, lasting. I have known young women under thirty years of age to become permanent invalids, with little hope before them of obtaining relief from their sufferings. Time sometimes does much; and if the patient can rest she may gradually improve, but among those who have to exert themselves this seldom occurs.

In thus sketching the outline of the stages through which the uterus passes when its involution has been defectively performed, you must not suppose that there is any well-defined division between them. One passes imperceptibly into the other, and numerous modifications of the symptoms and conditions I have described are daily to be met with, as well as many complications from irritation or inflammation of the neighbouring viscera, especially of the bladder, while the digestive functions nearly always become imperfect. Nor are you to suppose that all this long train of symptoms sets in always at once, or dates necessarily from the most recent pregnancy. On the contrary, it often commences long previously; perhaps after the patient's first or second labour, involution of the uterus was imperfectly performed; still the organ remained sufficiently healthy to permit of pregnancy again occurring, and of utero-gestation proceeding to the end of the full term, then labour occurring, unless great care be taken—and sometimes even with the greatest care—involution is still more imperfect than before, and so the case proceeds, till the uterus, unfitted for the office it should perform, allows of the escape of the immature ovum, and a bad miscarriage or premature labour occurring, all the patient's sufferings are laid down to it, whereas the evil had commenced a long time previously.

In dealing with weakly, delicate women, it is sometimes impossible to prevent the occurrence of defective involution after parturition, but these cases are the exceptions; and without doubt all the troubles and sufferings I have described are in general preventible, and such of you as are engaged in the practice of midwifery, should inculcate on your patients the absolute necessity which exists for their giving the uterus time to recover itself after childbirth, and you should point out to them the risks they run if they neglect your advice. This is clearly your duty, and it is a duty which should never be neglected.

CLINICAL LECTURES ON SYMPTOMS.

Delivered in the Wards of the Hospital.

By FREDERICK T. ROBERTS, M.D., B.S., F.R.C.P.,
Professor of Materia Medica and Therapeutics at University
College; Physician and Professor of Clinical Medicine at
University College Hospital, &c.

LECTURE V.—ON LOCAL SYMPTOMS.

IN order to give you some comprehensive notion of the local symptoms with which you are likely to meet in different combinations, I have arranged them, like the general symptoms, in certain groups, which we will now briefly consider.

I. ORDINARY MORBID SENSATIONS.—These are of very variable nature, including, in addition to local pain and tenderness, such feelings as mere discomfort, weight,

tightness, fulness, dragging, heat or burning, coldness, and many others. They may be associated with different structures, and are not specially connected with any one of them, although by attention to their situation, intensity, characters, and other points, they may usually be referred to some particular organ or structure, or may even indicate a particular disease. These local sensations often require careful investigation, and it must be borne in mind that they by no means necessarily correspond in situation to that of the disease upon which they depend, frequently being referred to a region more or less remote from that of the morbid condition which causes them.

II. PECULIAR SENSATIONS.—Certain systems and organs have peculiar feelings associated with them, some of which are present in the healthy condition, but are liable to be modified in disease, while others are only developed in different morbid states. These not uncommonly constitute important local symptoms, and ought always to be considered independently of the sensations referred to in the previous group, although there is no absolute line of demarcation between them, for the sensations now under consideration may also be of a painful character. The special senses afford the most prominent illustration, each of which has its own peculiar sensation, affected in various ways in disease. The nervous system has also particular sensations connected with itself, such as vertigo or giddiness; and these are also manifested in the skin and certain mucous surfaces by numbness or loss of sensibility, tingling, itching, creeping, exalted sensibility, and other feelings. There are various sensations met with in nervous affections, which cannot be defined or described. Abnormal sensations may further be associated with movements, as in the case of nervous motor disorders; palpitation of the heart; the pulsation of aneurisms; movements in the abdomen, affecting the stomach, intestines, or uterus; and retraction of the testes. In relation to the alimentary canal, we find the special sensations connected with deglutition; those of appetite and thirst, very often affected; nausea; and those associated with defecation. The respiratory organs afford an illustration in the feelings belonging to different forms of dyspnoea; the urinary apparatus in those connected with the act of micturition.

III. EXTERNAL OBJECTIVE SYMPTOMS.—I would include under this group all local phenomena connected with structures that are superficial or easily accessible to the observer in ordinary examination, so that they can be seen or handled, and thus these symptoms are determined usually with ease and complete certainty. Many of them are at once evident, while others have to be ascertained by more or less careful investigation, bordering in some instances upon what might be fairly termed skilled physical examination. I would therefore impress upon you the fact that some of these symptoms, although so obvious and readily recognised when looked for, require attention and practice on your part in order to do this in a satisfactory manner. This part of clinical examination belongs both to medical and surgical practice, and you will learn more and fuller details regarding these symptoms from the instruction you receive in the surgical wards and classes. It will suffice if I indicate the parts with which they are associated, and the nature of the phenomena which you have to take into consideration. The structures to which you have to attend in this connection are:—

1. The skin and subcutaneous tissue generally.
2. The face and head, especially the lips and mouth, the nose, the eyes and their appendages, and the ears.
3. The hair in different parts of the body.
4. The bones, periosteum, joints, and muscles of the limbs, and of other parts that are accessible to examination.
5. Certain glandular organs, namely, the external lymphatic glands; the thyroid; the salivary glands, especially the parotid; and the testes.

6. The superficial veins and lymphatics; and the arteries of the limbs, as well as others that are within reach of ordinary examination.

Now, in pointing out the objective clinical phenomena that may be found associated with these different structures, it will be at once understood that I do not mean that each of them presents all the symptoms mentioned, and a little consideration will enable you to understand which of these symptoms you may expect in connection with each several part. They may be arranged thus:—

1. Local increased heat or coldness, evident to the touch, or ascertained by the thermometer. This class of phenomena is of course only noticed in superficial parts.

2. Change of colour, especially abnormal redness, which is of very common occurrence in connection with the skin and mucous surfaces. The altered colour may, however, be revealed by pallor or whiteness, blueness or lividity, pigmentation, &c. In this relation change of colour of the hair may be mentioned.

3. Tumefaction, swelling, or enlargement. This is a symptom very frequently met with, and it may be associated with almost all the structures enumerated. It often requires careful investigation, not only as to its situation and degree, but also as to the sensation it affords to palpation, such as pitting, fluctuation, a brawny feel, or more or less hardness. Swelling or enlargement constitutes one of the most important symptoms of external abscesses, tumours, and other obvious morbid conditions; as well as of many diseases of the features, of bones and joints, of the external glandular organs, and of the vessels. Not uncommonly it is accompanied with marked deformity, especially in the case of the joints. Local oedema or dropsy of the subcutaneous cellular tissue is an important cause of superficial swelling.

4. On the other hand, there may be more or less local diminution in bulk or wasting, requiring attention as a prominent symptom. This may be noticed, for example, in connection with the skin, bones, muscles, joints, and glands. Atrophy or loss of the hair may also be alluded to here.

5. Without entering into particulars, it will be sufficient to mention the following external symptoms, which are of common occurrence, namely, diminution or excess of normal secretions, especially of the sweat, giving rise to local abnormal dryness or moistness of the skin; deposits on surfaces; morbid discharges and hæmorrhages; ulcerations, gangrene, and allied conditions; cutaneous eruptions of various kinds; and the presence of animal or vegetable parasites.

6. Changes affecting the mobility of parts. These may be produced by many forms of swelling or enlargement, but they are of chief consequence in relation to joints. When these structures are diseased, their movements, both active and passive, are often more or less seriously interfered with; on the other hand, occasionally their passive movements are too easily effected.

7. The objective sensations brought out by the more careful examination of diseased external parts, especially by manipulation, affords often most valuable clinical signs. This part of the subject belongs more especially to surgery, and I will content myself with mentioning the creaking or crackling sensations, or even sounds, elicited in the movement of certain diseased joints; the feeling of adhesion of the skin to underlying structures, and the pulsation of aneurism.

(To be continued.)

DR. GEORGE H. KIDD has been nominated President of the Dublin Branch of the British Medical Association for the ensuing year, and will deliver an address at the annual meeting to be held on the 25th instant.

THE LAWS WHICH GOVERN THE EXCITING AGENTS OF EPIDEMIC, ENDEMIC, AND INFECTIOUS DISEASES.—No 1.

By JOHN GROVE, M.D.

THE germ theory of disease is now attracting the attention of scientific men, as well as physicians, witness the latest conclusions of Prof. Tyndall on "Floating Matter in the Air." It has survived its period of infancy, it is now in its adolescence, and seems destined to enjoy a healthy, long, and useful life.

As one of the pioneers, and perhaps, one of the early workers, on the germ theory, it is a pleasure to see the enthusiasm with which this theory has been received. When in 1842, 1847, and 1849, I wrote about the Laws of Disease, the majority of the profession did not seem disposed to admit my theories, though I had the support of some of the best minds and the most thoughtful of that period.

Retired from the active work of practice, enjoying the *otium cum dignitate*, which fairly belongs to one who has borne the heat and burden of medical practice in our great metropolis, I feel that the time has come for me to review what I did so far back as 1849, and to show the young members of my profession, that even in those days there existed some knowledge of the germ theory, that the work of the present day was largely foreshadowed. Except perhaps Dr. Farr and a few others, not many of my *confreres* survive. A few modern writers have kindly mentioned my name in connection with the germ theory.

The following paper was one of my earliest contributions on the subject, it is as true now as it was in 1849 :

"There is no science in which a correct definition of words is of so much importance as that of medicine. "Words," said a late divine, "are an amazing barrier to the reception of truth." These remarks have a peculiar bearing on the state of our knowledge of epidemic diseases. When the pestilence of 1839 was sweeping away Her Majesty's subjects, the reproach of indecision and diversity of opinion among the medical profession was unhappily but too well merited. If we analyse the cause of all this, it will be found, not so much in the deficiency of our actual knowledge, as in the uncertainty of the terms and expressions made use of in the endeavour to impart that knowledge.

A student (and I believe we are all students on this subject) has barely entered on the investigation of pestilential diseases before he is arrested in his progress for a definition of miasms, mephitic vapours, exhalations, emanations, morbid secretions, effluvia, specific secretions, virus, animal poisons, and many other terms equally vague and unsatisfactory. Then come the words "infection" and "contagion," and here he finds confusion and discord enough to damp the energies of the most ardent spirit in its anxious search after truth. The great bulk of those who endeavour to fathom this subject, generally abandon it in despair; but occasionally one spirit more ventures than the rest essays to put in order the heterogeneous materials he finds scattered in works on medicine, chemistry, and history in particular, and those on science generally.

With this introduction I now proceed to the further elucidation of that view which holds, that all pestilential and infectious diseases are due to the existence and development of some form of matter endowed with the properties of life.

It is customary with the expounders of new or but partially received theories, to make outrageous efforts to demolish the arguments and pervert the facts of all those who, with contrary opinions, have come before them. Truth, however, is like light, and speaks for itself. We do not want to be told the mode by which the electric light is produced to discover the murky figure our otherwise luminous gas presents in the company of its antagonist.

Before plunging into the troubled water, it becomes necessary to say something of disease in the ordinary acceptance of the term.

The human body in a state of health is composed of a definite number of elements or forms of matter, combined in a wonderful and mysterious manner by the physical forces inherent in their ultimate particles, (a) It is to a disturbance of the equilibrium of these forces, or, in other words, to a derangement of their normal operation, that disease must primarily be referred. Reveillé (Paris) said: "However numerous the causes of disease may be in appearance, they may yet be reduced to three principal ones—wounds, poisons, and moral or physical organic super-excitement;" and he was not very far from the mark. A more simple view still may, however, be taken under the terms matter and force, or any compound word which shall convey their combined signification. Liebig thus defines disease:—"Disease occurs when the sum of vital force which tends to neutralise all causes of disturbance, is weaker than the acting cause of disturbance." "We study the complex in the simple, and only from the intuition of the lower can we safely proceed to the intellection of the higher degrees."—*Coleridge*, p. 41. These observations and quotations are made for the purpose of reducing the elements of our knowledge to their simplest form, and most concise expression. We have then to consider of matter and the physical forces in relation to each other; but, as our present inquiry is confined entirely to the consideration of pestilential diseases, it is quite unnecessary to pursue in detail the elementary principles of disease. It is sufficient to enunciate a law, if it be a primary law, to render clear and manifest all subsidiary or supplementary laws. We know, for instance, that living beings multiply by the faculty inherent in them of reproducing beings similar to themselves. But, though this faculty is common to all, there are subsidiary laws regulating the mode of reproduction or generation, which are readily comprehended when the primary law is understood.

Thus, having stated the primary law of disease to be a disturbance of those forces which in health keep the human fabric with all its functions in equilibrio, we have to interpret those laws which are specially concerned in the production of epidemic diseases.

Without further preliminary let us take three diseases which are acknowledged to merit the epithet epidemic. The disease I will mention is one that attacks the vegetable creation, and is known by the name of the vine mildew; this disease prevailed extensively in the years 1849 and 1850. The second I shall refer to, is that known as the epidemic apthous disease of cattle. And the third, that known as measles among the human species.

1st. The vine mildew is a parasitic vegetation, so generally known as not to need description here. Those who are familiar with its microscopic appearances, cannot fail to trace and understand how powerful must be its influence in causing a disturbance of the healthy functions of the plant upon which it becomes extensively developed. The leaves and leaf-stalks, the fruit and fruit-stalks may be alike equally covered with this seeming eruption. Dr. Lindley describes its habitat as on the leaves and green parts of vines, and as destroying the functions of the skin of the parts it attacks; but the dark skin of the forced grape becomes equally affected with the leaves and green parts, and the premature shrivelling of the diseased grape would seem to indicate an appropriation of its juices by the parasite. This disease manifestly depends on the development of the spores of the oidium, and their rapid and extensive faculty of reproduction. In this instance of disease, the force or power of

(a) Since writing this paper, I have read the Review of Carpenter, "On the Mutual Relation of the Vital and Physical Forces." I have, further on, as an explanation of the use of the term, "physical forces" inherent in particles of matter, suggested the comparison between the vital force and light. That the former bears a similar relation to the physical forces which light does to the rays of the spectrum.

growth in the cidium is superior to that of the tissues of the vine on which they grow. It is on the same principle that the muscardine, or silkworm disease, occurs. The parasite *Botrytis Bassiana*, when communicated naturally or by inoculation to the silkworm, exercises a force of vital action beyond that of the victim's tissues; in fact it would appear that this process must be regarded in the light of cellular endosmosis, for the germ of disease is a simple cell, and were it not to overcome the cellular force of the insect, it would obtain no sustenance; for it can hardly be conceived, that the animal is destroyed by the mechanical pressure exerted by the extension of the parasitic growth. Taking this view of the matter, we arrive at the law discovered by Dutrochet, the law of endosmosis and exosmosis, by which the vitalised cell-wall maintains a communication with the cells of the insect's body; it is, therefore, most certain, that if there were not predominating vital force in the cell-wall of the parasite over that of the insect, the latter would remain intact, and the former would fail to increase and multiply.

We are now conducted to that property of all living beings, the power of reproduction. It may be thus expressed,—as the faculty of self-multiplication.

In this faculty we recognise a wide difference between organised, or living bodies, and inorganic matter, with its relation to the physical forces, or even the physical forces themselves, for wherever inorganic matter increases, it is by addition or *ab extra*, as in crystallisation. In the development of the physical forces, as heat, light, electricity, and chemical affinity, it has been shown by Professor Grove, that as they are correlative, each convertible into the other, so they are only modes of force, and that for the communication of this force from one body to another there must be a subtraction from the one and addition to the other; and that in the act, the one has lost exactly what the other has gained.

Now, the vital force of a plant not only increases its own force, but multiplies it indefinitely, in new and independent existences, which again repeat the process, these again continuing in a constant and uninterrupted line. Whatever be the form of matter endowed with life, it has definite relations and characteristics, and a specific sphere of action or destiny. It is by the relations and characteristics of matter and force that we are able to comprehend their nature and properties.

If we require to convert the one into its elements, or to resolve it into other forms, or if we desire to direct or control the other, our efforts would be fruitless unless we possessed some knowledge of the objects we wish to bring under our subjection; thus, whatever may be the exciting cause of epidemic diseases, it is equally important that we should hold some rational opinion on the subject. At present, I have only mentioned the vine mildew as an epidemic disease of vegetation; but there is a great variety of similar or analogous affections due also to the development and reproduction of parasitic vegetation which I have already referred to.

I will now allude to the second form of epidemic disease mentioned, viz., the epidemic aphthous disease of cattle. In the years 1839, 1840, and 1841, this epizootic prevailed extensively in England and Scotland, in France, and other portions of the Continent. The reports both foreign and domestic, concerning the affection are given with abundant detail, great truthfulness, and much simplicity. The reader cannot fail to notice the almost unvarying testimony given in favour of the highly infectious nature and extensive propagation of the disease-producing agent. It is enough to say, that the common reports show the indisputable fact, that the cattle-markets formed foci of infection; there, diseased and healthy animals were mingled together; the healthy often fell ill before they arrived at the farms of their new masters; there they tainted the pastures and contaminated the stalls; the cow-leech who examined their mouths was frequently observed to have given the disease to other stock, and on other farms, by the infectious matter attaching to his person or his clothes. Indeed, the extension of the disease by infection, and the multiplication of the matter

of infection, were proved beyond all doubt. Further, the disease could be propagated by inoculation. Here I would impress the necessity for observing the analogy between this affection and the epidemic disease of the vines. In using the word *analogy*, let me state the true and proper meaning of the term: "It is the sameness of the end with the difference of the means."

All plants and animals breathe; the same end is accomplished, however, by different means; the stomata of plants, the spiracula in insects, the gills of fish, and the lungs of man, are analogous organs.

The epidemic cause, whatever it be, has for its end extensive disturbance of the economy of all those living beings on which its influence is exerted, and the conversion of other matter into a condition capable of exercising the same power; in other words, its end is reproductive.

Dr. Sutherland, in his Report on the Cholera, cannot avoid touching on this peculiarity. He says, "It appears as if some peculiar organic matter, which constitutes the essence of the epidemic, when brought in contact with other organic matter proceeding from living bodies or from decomposition, has the power of so changing the condition of the latter as to impress it with poisonous qualities of a peculiar kind similar to its own." And this is doubtless the fact; but, as far as our present knowledge extends, we have no means of explaining the process by which matter impresses other matter with properties similar to its own, except we assume that such matter possesses the property of life.

The observations made on the epidemic diseases of cattle apply equally to the third disease I have mentioned for comment, viz., measles. I shall, therefore, here only allude to the fact, that measles, or rather that which causes the affection, may be multiplied, either by inoculating with the blood, or the serum from the vesicles of a diseased individual, which is truly by contagion; or multiplication may occur by the transmission of the infectious matter by a variety of means from place to place, or from one person to another.

Thus it appears, that, in the three diseases selected, there is a reproductive faculty in the matter which engenders them; and that, during the development of this faculty, a force or power is exercised on the vital fluids and tissues of plants and animals superior to that force, or those forces which sustain them in health and vigour. That this law applies, with certain modifications, to all pestilential and epidemic disease will be made manifest in the sequel.

If, then, it be true, that the matter which causes epidemic disease has the power of reproducing its kind, it follows of necessity that that matter should be subject to the same laws as all living beings; and if we take reproduction as the primary law, the germs of disease in their relation to the material world ought to show an obedience to the same subsidiary laws which govern and affect the germs of plants and animals.

We find that all living beings produce their kind, to which we give the term "reproduction." I place this therefore, as a primary law, and consider all other laws as secondary. The secondary laws I divide into objective and subjective, using these words in their English sense.

Under the objective laws I regard—

1. The diffusion or dispersion of germs.
2. Their static existence.
3. Duration of active existence.
4. Period of development.
5. Intermittent reproduction.

Under the subjective laws I regard—

1. Seasons of activity.
2. Climatic influence.
3. Relation to latitude.
4. Subjection to physical forces.
5. Influence of locality.

(To be continued.)

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 13TH.

The President, JOSEPH LISTER, F.R.S., in the Chair.

ADJOURNED DISCUSSION ON MYXŒDEMA.

Dr. HERON described the case of a man who that day had come under his notice at Victoria Park Hospital, and whom he had brought for exhibition before the Society. This patient was a publican, but not a drunkard, *æt.* 54, subject to gout. At 20 years old had had typhus, and suffered since from palpitation. His appearance was peculiar, suggesting albuminuria. The face was pallid; eyelids puffy; teeth well worn; arteries thick and stringy; hands and feet puffy, pitting on pressure; left ventricle of heart enlarged. The urine contained *no* albumen, and there was *no* retinitis. (Patient was shown).

Dr. GOODHART wished to draw attention to a case mentioned by Dr. Mahomed, which, during life, had exhibited the characteristic features of myxœdema, but examination of which, after death, did not confirm this view of its nature. The brain was peculiar and india-rubber-like; the heart was diseased; but there were no other unusual conditions of the viscera, and as to the true significance to be attached to the condition of the brain, Dr. Goodhart was in doubt. The connective tissue throughout the body was pervaded by jelly, which, on being analysed by Dr. Stevenson, was found *not* to contain mucin in any abnormal amount. It was true the state of the brain showed some departure from the normal, but microscopic examination of the tissues demonstrated a freedom from disease. The nervous symptoms in this case were entirely due to generalised conditions, and it proved that clinical states, agreeing closely in their characters, may be produced by widely-varying causes. Dr. Goodhart could not agree that chronic œdema alone would produce a condition of tissues in which mucin would be largely developed. Dr. ORD's theory of a peculiar cell degeneration offered an interesting study, but there was danger to be feared from the too active spirit of pathological speculation prevalent in late years. He considered that cell proliferation had been too readily rejected in favour of degeneration as a probable cause of the conditions noticed. He quite agreed that in the future many different states, now widely separated in systematic descriptions, might be allied under a single descriptive head, but, notwithstanding, he could not think that myxœdema would ever come to be generally regarded as a form of chronic Bright's disease, as maintained by Dr. Mahomed.

Dr. MARCET also dissented from Dr. Mahomed's view, for reasons thus epitomised—the disease is commoner among women, and rare among men; the skin presents an appearance very unlike mere œdema; albuminuria, when it occurs, only sets in late in the course of the disease; the nervous symptoms are peculiar in myxœdema, including dulled intellect, and sensibility (hence termed cretinoid). It was necessary to determine the pathology or essence of the disease, and from post-mortem appearances it had been made out that this was primarily associated with malnutrition, whence malformation, rather than degeneration of tissues, ensued. The truth of this could be further supported by chemical analysis, by which it had been proved that the tissues comprised only partially-formed material, consisting of phosphoric acid, potash, and albumen. Had degeneration been in process, the products would consist of fully formed materials, but this was not the case. Mucin was not correctly regarded as characteristic of myxœdema. Dr. Dickinson described a substance, in all respects resembling mucin, formed by the action of dilute hydrochloric acid on muscular tissues, and in this connection it would be of interest to test various parts of the bodies of myxœdematous patients, with a view to discovering in them traces of de-alkalised fibrin. Another interesting feature was the condition of the urine, which, in these patients, had been described as containing less urea than usual. This, however, would have no great importance, as significative of the disease, since it varied with the amount and nature of food, exercise, &c., &c. Estimation of the chlorine in the urine, however, might

afford very valuable assistance towards determining the nature of the disease, since it undoubtedly diminished in quantity in ordinary œdema. The respiratory process likewise offered a means of diagnosis of considerable value; temperature was always reduced in myxœdema, and the cause of this required to be determined.

Dr. F. TAYLER recorded the history of a private patient, the wife of a clergyman, who presented all the usual symptoms of myxœdema. She was very deaf, and had cramp-like pains in her thighs; patellar-tendon reflex was normal; menstruation regular, but discharge increased in amount. Patient had two children, and dated oncoming of the disease from birth of youngest child, two years ago. Her father was insane, and confined in a lunatic asylum. Her mother was a slim and active woman up to 52 years of age, when she began to grow stout, and died at 62 from general decay, but, from the description given of her condition, little doubt could be felt that she was the subject of myxœdema. Jaborandi in the case of the living patient had restored sensation to the hands, and stimulated the perspiratory secretion.

Dr. W. B. HADDEN explained that the symptomatology of myxœdema might be summed up thus (1) retardation of intellectual functions; (2) slowed bodily movement; (3) reduced temperature; (4) condition of urine; (5) mucoid state of skin; (6) condition of thyroid gland. He suggested it might be due to affection of the sympathetic nervous system, this theory fitting in with various symptoms of the disease. He had recently examined different parts of the sympathetic system in a case which died in St. Thomas's Hospital, and found lesions in it, and in the medulla.

Dr. SEYMOUR TAYLOR considered that safe theorising could only commence in the post-mortem room. The facts there revealed ought not to be quoted to explain preconceived ideas of disease. He had himself made sections of the spinal cord and brain of myxœdematous patients. He found them persons subject to mental worry, and in the first descriptions they had even been called cretinoids, as an indication of their mental weakness. He wished to know with what form of Bright's disease myxœdema could be associated, none appearing to him at all to resemble it. He would not advance a theory of the myxœdematous condition, feeling that there was not sufficient evidence to found it upon. He believed, however, that the lesion of chief importance would be found to be in the nervous centres.

Dr. DYCE DUCKWORTH thought, in regard to Dr. Mahomed's suggestions, that the Society would most satisfactorily discuss clinical rather than pathological phenomena. On the former grounds he was unable to accept Dr. Mahomed's conclusions, and he agreed with Dr. Goodhart that similar conditions might be productive of very different morbid changes. He thought the condition of the urine sufficed to separate myxœdema from Bright's disease, and it would be really remarkable to find that there existed a form of chronic Bright's disease of which so few instances have been recorded. Dr. Mahomed's views, however, had been invaluably serviceable in awakening discussion on the subject.

Dr. ORD agreed with Dr. Duckworth, and in respect to clinical features remarked that myxœdema was more common in women, and that albuminuria was never existent in early stages of the disease, not being always found later on even. The integuments were pervaded by a thick growth; there was no perspiration; hair scanty and ill-nourished; body temperature low; thyroid gland diminished in size; a remarkable train of nervous symptoms, speech, thought, and movement being all retarded, while not being really *imperfect*. No loss or exaggeration of patellar reflex. Complications arose as disease progressed. Patient became unreasoning, suspicious, finally passing to stages of dementia and coma; in some cases debility and uræmia induced death. The pathological conditions thus far made out included altered connective tissue *throughout the body*, it being swollen, richer in nuclei, with prominent fibrillar elements, and rich in mucin. All formed tissues underwent atrophy, as in the hair bulbs, sebaceous and sudoriparous glands, heart, liver, kidney, central nervous organs, &c. The elastic and transparent tissue showed abundant overgrowth. The opinion at first sight suggested, viz., that cases of myxœdema might be instances of Bright's disease without albuminuria, was negated by fuller study of the symptoms. Dr. Mahomed would extend the signification of Bright's disease to include the myxœ-

dematous condition, thus amplifying Gull and Sutton's views regarding arterio-capillary fibrosis. The fact that in certain cases of myxœdema renal changes, as in Bright's disease, had been set up, raised the question as to the real meaning of the latter term, which might, indeed, be extended to almost interminable lengths. Dr. Ord went at length into the task of contesting the points raised by Dr. Mahomed, the result being, however, to bring him (Dr. Ord) into agreement with previous speakers in the same connection. Dr. Hadden's theory, Dr. Ord continued, raised the whole question of the trophic function of the sympathetic system, of which, it had to be said, evidence sufficient was not forthcoming. Dr. Goodhart's views were approved by Dr. Ord, whom Dr. Marcet had anticipated with respect to the chemistry of the tissues. The question of heredity of myxœdema had been raised for the first time by Dr. Tayler. In conclusion, Dr. Ord said that though he had freely criticised the theories of others, he was not himself prepared to offer one which should afford explanations of all the phenomena discussed.

OBSTETRICAL SOCIETY OF EDINBURGH.

The Society met on Wednesday, January 11th, at eight o'clock p.m.

Professor SIMPSON, President, in the Chair.

Dr. Cappie exhibited a specimen showing the "Interlacement and curious knotting of the umbilical cords in a case of twins." One child died soon after birth, the other is still alive.

Dr. Waugh also exhibited an "Umbilical cord of considerable length with a knot on it."

Dr. Croom exhibited an "Acardiac fetus in a case of twins." Also a set of Dr. Emmet's instruments for performing colporrhaphy.

Dr. Simpson exhibited a "Three months fetus with a dorsal cyst," and a case of "Exomphalos," which is to be the subject of a paper at the next meeting of the society.

A NEW INSTRUMENT FOR CRUSHING THE HEAD OF THE FŒTUS.

Professor SIMPSON read the history of a case of basilyasis, an operation for crushing the base of the cranium by an instrument invented by himself and called a basilyst. The instrument consists of two blades the one fitting into the other and terminating in a gimlet-like point which it is intended to screw into the base of the cranium and which, when fixed, destroys the part by separating the blades. The instrument can be applied to different parts of the cranium the ultimate result being the same. The advantages claimed for this instrument over those now in use for crushing the head of the fetus, are that the base of the skull is more effectually destroyed, and that the instrument working within the head of the fetus is not so likely to injure the maternal parts. The case described was the first in which the Professor had had the opportunity of trying the instrument, and the success which had attended his efforts were such as to induce him to lay the results before the society.

Dr. P. YOUNG thought that the instrument was based on the most scientific principles, and believed that its advantages would be greatly appreciated, for it was the base of the cranium which was the most unyielding, and which gave the greatest trouble in cases when it was found necessary to break up the cranium. He should certainly use the basilyst at the first opportunity.

Dr. HALLIDAY CROOM related the history of a case where he had used the instrument, but with indifferent success owing, he thought to the use of Professor Simpson's earlier model, the screw of which was blunter than the one now before the Society. He also thought that the instrument would be most useful in those cases where the head had become fixed in the pelvis. In some positions of the fetus he also feared that there might be some difficulty experienced in fixing the screw in the base of the cranium. Professor Simpson briefly replied.

Dr. PETER YOUNG gave the history of a

CASE OF VAGINAL ENTEROCELE ILLUSTRATED BY A DIAGRAM.

It appeared that during labour, which was slowly progressing, the patient felt some pain in the pelvis, which did not appear natural to her, and sent for Dr. Young, who, on exami-

nation, felt a soft tumour in the posterior vaginal wall, pressing into the vagina. Suspecting the nature of the tumour attempts were made at reduction, which was readily effected, and the patient was subsequently easily delivered. The recumbent position was maintained for some weeks after delivery. On going out one day the enterocele returned, but was, as before, easily reduced, she, however, subsequently took cold, suffered from a severe attack of pelvic peritonitis, from which she, with difficulty, ultimately recovered with a radical cure of the enterocele, from the gluing together of the peritoneal surfaces in Douglas' pouch. The literature of the subject was then discussed, and the diagnosis, and best methods of treatment suggested.

Professor SIMPSON thanked Dr. Young for his valuable communication to the Society, at the same time stating that he had never met with such a case; his knowledge of them being only derived from books.

Dr. CROOM held that, in anteversion of the uterus there was always more or less of intestation in Douglas' pouch.

Dr. R. MILNE MURRAY then read the history of a—
DIFFICULT FACE CASE, COMPLICATED WITH SHOULDER DYSTOCIA FROM AN UNUSUAL POSITION OF THE ARMS, illustrated with diagrams and photographs.

Appended to the notice of his case was the following note:—"It is hoped that the Fellows who have had cases of Arrested Face, will either give their experience at the meeting personally, or send a note of them, in the tabular form at page 3 of the Billet, to Dr. Hart, 65 Frederick Street, Edinburgh. If a sufficient number of cases be given, the result will be drawn up and printed as part of the Discussion."

The child was born dead with its arms pinioned as it were behind its back, and probably causing the difficulty in the delivery. As the hour was late the discussion was adjourned to a future meeting together with the following papers:—

Case illustrating the Importance of Accurate Pelvimetry, with Description of a New Method. By Dr. Wm. Turner, Civil Hospital, Gibraltar.

Case of Pregnancy in a Woman at the Age of Sixty-two. By Dr. W. J. Kennedy, Penicuik.

Case of Exomphalos, where the Intestines of the Fœtus Presented during Labour; with Specimen. By Professor Simpson.

Special.

THE "MEDICAL PRESS AND CIRCULAR" REPORT ON THE SMOKE ABATEMENT EXHIBITION.

No. I.

THE subject of smoke prevention is one which should commend itself to all. To medical men it should be especially acceptable. Those of our profession who live in or near large towns must see almost daily cases of bronchial or pulmonary disease aggravated, if not produced, by the soot-laden atmosphere in which the patients spend their lives. The post-mortem table reveals the fact that in all adult lungs a varying amount of solid carbon is found in the form of particles which have been inhaled. Every one, in fact, possesses a "miner's lung" on a small scale. All of our readers presumably possess fireplaces, and are therefore doing their share of adding to the smoke around them. Those of them who live in or near London would find both pleasure and profit in a visit to South Kensington. Not only are numerous appliances to be there seen for the prevention or consumption of smoke, but ventilation, lighting, and warming are all incidentally illustrated.

In the following brief account of the exhibits, more especial attention will be directed to those which possess some hygienic advantage.

OPEN FIRE GRATES.—All the smokeless fire grates exhibited may be divided into two classes—(1) in which the fire is such that no smoke is produced; (2) in which the smoke is allowed to form, but afterwards heated so strongly as to ignite, and convert the solid particles of carbon into the oxides of carbon (carbonic acid and carbon monoxide—chiefly the former). The first method is easily adopted by burning a smokeless fuel, such as charcoal, coke, gas, anthracite coal,

or some patent fuel. Charcoal is not in much favour in this country, although extensively used on the Continent. Coke will not readily light or burn alone, but with gas, on Dr. Siemen's plan, it can readily be lighted, and the gas can then be turned out, only to be relit when needed to brighten up the fire. Grates on this principle are exhibited by Mr. Hammond, of Charing Cross, Messrs. Waddell & Main, of Glasgow, Messrs. G. Wright & Co., of Queen Victoria Street, The Dawson Economic Gas Company, Limited, of Westminster, Messrs. H. and C. Davis & Co., of Camberwell, and Messrs. S. Leoni & Co., of the Strand. The principle can easily be adapted to ordinary grates. Of asbestos gas fires there is a great variety to be seen in action.

Numerous varieties of anthracite coal are exhibited by different companies, together with grates to burn the same. It may as well be stated that anthracite can be burnt in any ordinary grate with a fair draught. Vertical bars are preferable, it is said, but it is not really material. If the fire is lit with ordinary coal, not the slightest difficulty need be experienced in burning anthracite throughout the day. With care it is even possible to use it in lighting a fire.

Specimens of patent smokeless fuel are exhibited by the Bristol Patent Coke Company, Dynevor Coal Company, Eiford Colliery Company, Graigais Merthyr Company, and Messrs. J. Hall & Co., of London.

The same end is also attained with ordinary coal either by lighting it at the top, or feeding it from the side, back, or below, so as to compel the smoke from the fresh fuel to travel upwards through the red hot coals on the upper surface, where perfect combustion ensues, and only clear colourless gases pass up the chimney.

Messrs. Edwards & Son, Great Marlborough Street, exhibit a grate in which the fire is lighted at the top, and allowed to burn downwards, a sufficient supply of coal for the day having been previously placed in the grate. A movable iron blind conceals the unburnt mass of black coal. This grate is, therefore, smokeless. It is also slow combustion and ventilating, a chamber for introducing warmed fresh air into the room being constructed behind the fire.

Mr. H. T. Grainger, of Camberwell, has on view a grate in which the fire burns downwards, and is therefore smokeless. It may as well be remarked, *en passant*, that the principle of lighting the fire at the top and letting it burn downwards can easily be adopted in any grate. The fire will be smokeless until fresh coal is put on at the top.

Mr. T. Goodchild, architect, of Duke Street, Adelphi, exhibits diagrams of an economic, smoke-consuming, open fire grate. The fire is lighted at the top and burns downwards. There is a blower to regulate the draught, and the space beneath the fire is closed in with an air-tight ash-pan, thus rendering it a slow combustion grate.

Dr. Joseph Moore, of Thornton Heath, exhibits a grate in which the draught is downwards through the fire, so as to be smokeless; but in addition there is a small grated opening into the chimney in the usual position of the register, so as to allow the lighter portion of the fumes to rise directly into the chimney. The fire is fed in the usual way. The inventor claims that by his arrangement no more air is supplied to the fire than is actually needed for combustion, and thus the heat is retained in the room and draught prevented. The grate is also ventilating.

In both Saxon Snell's revolving fire grate exhibited by Messrs. Potter & Sons, of Oxford Street, and the Leopold reversible grate, brought out by Messrs. Rosser & Russell, of Charing Cross, the coal is supplied in the usual way, and, by using the poker as a lever, the fire-box is then reversed, so as to bring the fresh coal underneath.

Messrs. Martin's (of Blackfriars Road) fire grate has movable sides, which can (one or both) be drawn away from the fire, thus leaving a vacant space, in which coal is put. The side plate is then brought into position again, thus thrusting the fresh coal into the centre of the fire.

Mr. Hoole of Sheffield, exhibits a grate with side chambers, from which the fire is charged by a lateral movement of the poker.

Engert's fire grate has what is termed a coking box at the back, which is charged before lighting the fire, and the coal brought forward into the fire as required by moving forward an iron plate at the back by means of a screw arrangement, which can be worked by inserting the end of the poker in some holes in front of the bars, and using it as a lever.

Mr. E. R. Hollands exhibits a grate which is fed underneath. McMillan's undergrate coaling apparatus effects the same

end. It has the advantage that it can be applied to existing grates or kitchen ranges.

Mr. G. A. Spencer has a similar appliance.

Messrs. Brown & Green, of Bishopsgate Street, exhibit both a register grate and a kitchener, which are made smoke consuming by using an under coaling arrangement, consisting of a little trough, which is filled with coal and then thrust up into the fire.

Melville's patent shovel, invented by Mr. W. S. Melville, of Frederick Place, Mile End, E., is a most ingenious contrivance. It is a sort of box, which is opened, charged with coal, thrust into the fire between the bottom bars, and its contents discharged. All this is very easily accomplished by means of a mechanism which would be tedious to describe, but which is very simple in practice. The shovel can be had in different sizes to suit the varying sizes of the spaces between the bars in various grates, and has the merit of being cheap.

Several register grates are shown in which the fire is lighted in the ordinary way, and after it has burnt up, and the up current in the chimney is thoroughly established, the register door is closed, and the smoke compelled to travel downwards through the fire, and thence through a special flue into the chimney. With this plan it is obvious that there must be some smoke on first lighting the fire, and until the draught is sufficiently established to close the register door.

Messrs. Archibald Smith & Co., of Leicester Square, exhibit what they term the "wonderful" grate, inasmuch as the fire can be made to last forty hours without attention. A curved reservoir holds the coal, which falls down into the fire as required. It can be recharged while the fire is alight. It is also made as a ventilating grate in one size. The inventors claim that it will burn coal, coke, cinders, or anthracite.

Captain Clarke, of Taunton, exhibits a grate and range, in both of which the same principle of smoke consumption is adopted. The fire grate projects so as to radiate as much heat as possible into the room, and there is an air chamber around the grate for introducing warm fresh air.

Ingram's Kais Kapnos grate, made by Messrs. Clark, Bunnett, & Co., of Rathbone Place, is constructed on the same principle. It is made both ventilating and non-ventilating, or, as the inventor prefers to term it, "hygiastic" and "non-hygiastic."

The originators of the modern slow combustion grates, viz., the Derwent Foundry Company, exhibit a grate in which the same idea is used, and which is also a ventilator.

In all the grates on this principle the fire can be burnt in the ordinary way by simply leaving the ordinary register door open.

The principle of burning the smoke after it is formed is illustrated in a great variety of grates, stoves, and kitcheners.

Messrs. Barnard, Bishop, & Barnard exhibit a modification of their well-known Norwich slow combustion grate, which they term "The Glow." From an air chamber at the back of the fire a jet of highly-heated air plays on the smoke, and ignites it just above the fire.

The Coalbrookdale Company have a grate on view in which the same end is attained by passing the smoke through a chamber formed of fire-brick, and sub-divided by small partitions of the same material. This chamber becoming strongly heated, perfect combustion is assured.

The "controlled combustion" principle advocated by this company consists in having the bottom of the grate formed of a firebrick slab, perforated with several conical apertures, the larger end of the cone being downwards. The space between this slab and the hearth is closed by an ashpan, in the front of which are dampers. The combustion can thus be regulated, and it is claimed that the conical shape of the apertures facilitates the falling through of the ashes, and (when the damper is open) quickens the draught.

Messrs. Feetham & Co., of Clifford Street, have a novelty in the form of a smoke consuming dog grate. The opening into the chimney is small, and at the back; and a current of heated air is brought into the fire at the back. The same firm also have a smoke consuming kitchen range.

Mr. R. H. Griffin, of Guildford Street, has on view a ventilating and smoke consuming open fire grate. The smoke is burnt by delivering jets of heated air into, around, and over the fire.

Mr. S. Johnson, of Wood Green, exhibits diagrams of a smokeless dog stove.

The Sunderland open fire grate exhibited by Mr. Herbert Lea, of Warwick Street, has a chamber behind, into which, on

lighting the fire, the smoke is drawn through apertures in the back of the grate, and there burnt, the ordinary register being closed. When the fire has burnt up, and smoke has ceased, the opening into this chamber is closed by a valve, and the ordinary register opened, when the fumes pass up through it as in ordinary grates. On feeding the fire with fresh coal, the valves are again arranged so as to draw the smoke back until there is again a clear red fire.

Messrs. Musgrave and Co., of New Bond Street, exhibit their new "Ulster" grate in which the smoke is consumed by a blast of hot air passing in at the back. This is a slow combustion grate, and will burn for 12 hours or more without replenishing, as it has a receptacle for coal above and behind the fire, which is filled up in the morning, and from whence the coal sinks down gradually into the fire as required. This grate is also provided with a blower, in which there are numerous perforations arranged to form a design. This permits the fire to be seen, even when the blower is in use.

Mr. T. E. Parker, of Battersea Park, exhibits an open fire grate which consumes its own smoke.

The Radiator Range Company, of Cannon Street, display a grate which is smoke consuming, and also ventilating. The grate projects boldly into the room, and above it is a miniature dome to catch any little smoke that might arise from it. The smoke passes backwards into a back chamber, where it becomes ignited by meeting with a current of heated air. All the space between the fire and the mantelpiece being closed in, no air can rush up the chimney except what passes through the fire, and draughts in the room are thereby lessened. Pure warm air is introduced into the apartment from an air chamber behind the smoke flue.

Messrs. Steel & Garland have on view the "Kensington Smoke Consuming Grate," in which the smoke is similarly burnt by a blast of hot air. On first lighting, the smoke is allowed to ascend the chimney in the usual way, but when the draught is set up the register door is closed, and the smoke drawn back into a smoke flue, where it is converted into flame before passing up into the chimney. Behind the smoke flue again is a warm-air chamber, so that this grate is, like a few others, both slow combustion, smoke consuming, and ventilating. The specimens shown at South Kensington would adorn any room.

The Wavish Patent Fuel Economiser Company, of Cannon Street, exhibit a little appliance for lessening smoke termed the "Wavish Coal Economiser." This simply consists of a piece of wrought iron plate made to the size of the bottom of the grate, and rising through it a small cylinder open below, and perforated with small holes all round, but closed at its upper end. The bottom plate checks the combustion, while through the central cylinder air passes up, and is discharged in a highly heated state into the centre of the fire through the side holes, thus tending to perfect combustion. The invention can be applied to any ordinary grate.

Mr. J. G. Gray, of Forest Lane, also exhibits a little invention to reduce smoke, consisting of an open-grated false bottom, which is set obliquely in the grate. The fire is thus lessened below, but is thrown forward, while combustion is rendered more complete by the current of warm air which plays on the fire from behind.

Mr. J. T. Reeve, of Little Marylebone Street, exhibits a grate to which what he terms the "Calpean" smoke consumer is applied. This is simply a small fire-brick chamber placed at the back of the grate, with apertures leading to the fire in front and the chimney above. This is filled with metallic shavings. As all other outlet to the chimney is closed, all the fumes are compelled to travel through the apparatus on their way to the chimney. As they do so they impart their heat to the small shavings of metal which fill the box, and the latter, finally becoming red-hot, ignite the smoke. The apparatus can be adapted for existing grates at a small cost.

Before proceeding to consider ranges, stoves, and gas appliances, it will be as well to briefly describe some of the open fire grates which possess merits, but are not smoke consuming. We propose drawing attention to this class in our next.

AUGUSTUS C.J.

(To be continued.)

THE funds of the Belfast Royal Hospital have been increased by donations from Sir Edward Coey of 500 guineas, and Mr. Joseph Richardson, £50.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 18, 1882.

ANOTHER GUY'S DISASTER.

FOR a time deceitful calm has reigned with respect to the conduct of affairs at Guy's Hospital; those, however, familiar with the characteristic features of management of its internal details have failed to be convinced that any real improvement has been possible under a *regime* condemned by universal assent of all competent judges. How justly founded such distrust has been the history of last week abundantly shows; and once more we are brought face to face with the calamitous consequences attendant on that fatal want of judgment shown in permitting a continuance of defects declared at the outset of all the troubles to be capable and likely causes of irremediable mischief. It were useless to recapitulate once more the dreary catalogue of errors and disasters which lend such sinister interest to the chronicle of Guy's Hospital for the two preceding years. Again and again, as each new sin of omission and commission has been heralded to the world by the unavoidable publicity its results have secured to it, have warnings and protests been uttered from every quarter in which authority rightly reigns; but all in vain, as, apparently infatuated by a spirit of determined resistance to every suggestion of amendment, the responsible agents of Guy's ruin have persisted in the course mapped out in the imagination that has thus far led them astray. Harsh criticism, indeed, of acts thus suicidal in their tendency, has seemingly been fruitful only in multiplying them; unsparing disapprobation has followed each fresh departure from order, but notwithstanding, an in-

attentive ear has been constantly turned toward advice tendered without response, and Guy's is once more a reproach to medicine, and a bye-word among men. It may seem unduly severe thus to characterise an act which has been described as "misadventure" by an intelligent coroner's jury; but we must, at the same time, remember that the weight of censure contained in a recommendation to employ papers of distinctive colour for wrapping up poisonous drugs, comes with unusual significance from a body in whose hands lay power to impose a much greater penalty than that inflicted. It may be that Guy's is not the only hospital in which morphia is dispensed to the wards in similar coverings to those in which quinine is inclosed; but we venture to assert that in no similar institution within the metropolitan district is the administration of a character to permit indiscriminate mingling of deadly poisons and normal remedies in a common receptacle, by the regular ward attendants. It is the miserable system in vogue at the devoted transpontine charity, whereby the functions of the medical staff are in great part usurped by unprofessional hands, that deserves to be credited with this last misfortune, as it has been rightly blamed in turn with all those preceding it. Apart from those special considerations which lend importance to the names whereby the ward attendants are called—considerations, be it said, which it requires a special education to appreciate—there is absolutely nothing that can be urged in defence of a plan which practically leaves the lives of many patients to the chance workings of a woman's imagination.

In this last instance of "error," a female patient, on the high road to convalescence from typhoid fever, was suddenly poisoned by the accidental substitution of ten grains of hydrochlorate of morphia for a quinine powder ordered by the physician in charge of the case. Inquiry into the circumstances attending the death was, of course, instituted, and evidence was tendered in explanation of the fact that such a lamentable mistake could have been committed. Apart from the facts then revealed, pointing to the nature of the ordinary duties imposed upon the nurses; it is sufficiently startling to those accustomed to see the rigid caution exerted in regard to medicines at most hospitals, to hear that a quantity of morphia like that given to the patient, should, on any account, be entrusted to even the superior ward servant of the hospital. So long as women are permitted to hold the position of authority they assume at Guy's under the rule of those who have inaugurated the "new" system there, so long will the public continue to be shocked and scandalised from time to time by such occurrences as the melancholy one recorded last week. It is worse than foolish, it is criminal to pretend blindness in respect of the real cause of these constant departures from the usual current of events; and so long as no determined and successful attempt is made to restore order and safety to the management of a great charity like Guy's,—so long, that is as nothing is done to check the manifest tendency to disaster,—so long will the public continue to contribute its occasional victim of mismanagement.

Once before we have reluctantly given expression to the opinion that reform in this matter must be looked

for from without rather than through the medical profession, and now again we are constrained to utter the same warning. Things at Guy's Hospital are radically and seriously bad. A condition of affairs that admits the possibility even of such a catastrophe as that just recorded, is intolerable; and since the responsible authorities are unwilling to stir, or incapable of moving, for the purpose of bringing about much needed changes, then it is high time the duty should be assumed by an able and efficient extraneous power. We have no wish to waste words in condemning individuals just now; perhaps the profession will think with us that enough in this way has already been done; but, unhesitatingly, we do condemn a system of management so rotten as the internal administration of Guy's is proved to be, and we demand its reform as a public necessity.

DISORDERS OF THE MIND.

THE trustees of the Combe Trust are, indeed, fortunate in having secured the services of Dr. Yellowlees, who lectured under their auspices to a large and appreciative audience in Glasgow, on the 12th ult., and whose teachings certainly tend to perpetuate much of what was best and most useful in the work of Combe. Dr. Yellowlees is, of course, specially qualified to deal with the subject on which he discoursed. A leader in his own department of medical practice, the head of the largest, and one of the most admirably conducted, of the Scotch chartered asylums, and at one time medical superintendent of a public asylum in Wales, he has had ample and varied opportunities of becoming acquainted with all the phases of insanity, and that these opportunities have not been thrown away upon him, his writings, and the estimation in which he is held by his professional brethren, alike testify. But Dr. Yellowlees has other qualifications for a successful public lecturer, besides an intimate knowledge of his own subject. He has a rare command of language, and of apt illustration, a genial nature and quick sympathies which win the hearts of his audience, and a just appreciation of the range and limits of a popular exposition of a scientific subject. It sometimes happens that an accomplished specialist fails when attempting to expound popularly the results of his studies, just by reason of their profundity and minuteness which lead him to overshoot the comprehension of those who listen to them, making no allowance for the ignorance of outsiders and their unpreparedness to rise at once to the level of specialistic insight. But Dr. Yellowlees falls into no blunder of this kind. He never loses sight of the fact that in dealing with a topic like mental disease, he must be rudimentary if he is to be understood and instructive. He does not endeavour to make medical psychologists of his auditors, but with a just estimate of the way in which he can be of most service to them, he gives them such a general outline of mental disorders as ought to be known to all cultivated people. He warns them against a number of pernicious fallacies about the nature of insanity and its treatment, that are still in circulation, and he points out the most beaten and frequented of those highways that lead to the citadel of madness, and affords valuable hints as to how they may be avoided,

Dr. Yellowlees' lecture will doubtless be published in a separate form, so we need not attempt to summarise it, nor reproduce any section of it. We may, however, indicate its scope, and refer to a few points of peculiar interest which it includes.

After some prefatory remarks on the interest of his subject, and the spirit in which it should be approached, Dr. Yellowlees proceeds to trace the history of mental diseases from those primitive times when they could scarcely be said to exist, through the civilisation of Greece and Rome, when they were regarded as divine or demoniacal possession through the mediæval period when they fell under the care of the religious orders, through more modern epochs, when they were treated as if they were crimes, down to the present day, when they are regarded with enlightened humanity. In a generous eulogium on the pioneers of the present gentle and rational method of dealing with the insane, he showed how recently the beneficent changes which they inaugurated, were brought about, recalling instances that had fallen under his own observation, in which lunatics were kept chained up like wild animals. Adopting the main features of the classification of Griesenger, Dr. Yellowlees classed the various phases of disordered mind under morbid depression, morbid exaltation, morbid perversion, and morbid enfeeblement, and then went on to speak with some elaboration of the causes which produced these mind disturbances. Three things, he said, exhausted the brain—work, worry, and excesses. Few brains failed from over-work; many were ruined by the want of work. But worry was a very different thing. That meant, not work merely, but work, which, in spite of every effort, could not be satisfactorily accomplished, or which was accompanied by incessant agitation and distress. Worry was the disease of the present day, and ruined many a noble life, and to it Dr. Yellowlees felt inclined to attribute that actual increase of insanity which is, he has no doubt, going on. No doubt the apparent is much greater than the real increase of insanity, but when the apparent increase attributable to the recognition as lunatics now, of a great many persons who would not formerly have been so regarded, was allowed for, there remained a real increase to be ascribed to worry, and the excessive indulgence of animal passion and intemperance. Intemperance was one of the most fruitful causes of insanity, not only by directly poisoning the brain, and so originating organic disease, but indirectly by establishing and transmitting a tendency to nervous disease. Dr. Yellowlees' statement on this subject no doubt represents the current belief, and probably also the real state of the facts, but as regards the latter part of it, touching on the hereditary effects of intemperance, we would observe in passing that trustworthy statistical evidence is still wanting. It seems likely that the intemperance of the parent may entail insanity on his offspring, and striking instances have been adduced of the occurrence of a variety of neurotic diseases in the children of drunkards, but, on the other hand, cases might be quoted of families that have remained perfectly healthy throughout life, being born to habitually intemperate parents, and it is, of course, obvious that other diseased conditions and tendencies that are known to descend from one generation to another may co-exist with intemperance,

and be really accountable for instances of inherited neurotic disease that are attributed to intemperance. What is required is statistics showing the proportion in which the children of drunkards are affected by nervous diseases, in contrast with the proportion in which the children of unquestionably sober people are affected by them. And in such statistics insane drunkards should not be included, understanding by insane drunkards, those in whom intemperance is not a vice but a symptom of disorder of the brain. It is certain that the lapse into habits of debauchery of a previously sedate and abstemious man is sometimes the first symptom of an attack of insanity, and where this is so, it would be obviously unfair to trace the insanity of children to the intemperance, and not to the vice or degeneration of the nerve centres, of which the intemperance was itself an expression.

As an instance of the effect of sorrow and distress on the mind, Dr. Yellowlees mentioned that the failure of the City of Glasgow Bank sent two patients to his asylum, and as an illustration of the manner in which errors and prejudices connected with insanity are kept alive, he referred to a play performed in a Glasgow theatre in the course of the present season. The manager of the theatre applied to him for the loan of a strait-jacket, as it was absolutely required in the representation of the piece. He had the pleasure of telling the incredulous messenger of the manager that there was no strait-jacket, either old or new, in Gartnavel Asylum, and that the teaching of the play was mischievous and untrue. Unhappily it is not only in Glasgow that the stage is made the vehicle for the propagation of false and ridiculous notions, as to the treatment of insanity and the present condition of the insane. Not long ago we had produced at Drury Lane a silly melodrama, styled "The World," in which the lunacy laws were travestied, and asylums libelled or burlesqued in the most shameful and shameless manner. The ignorance of the author of the play of the law of lunacy and of asylum management, was truly marvellous, and so too was the way in which he packed his egregious misrepresentations together. But such distorted and preposterous pictures, or daubs we should perhaps call them, are not as Dr. Yellowlees says, without their injurious effects. Like the fabrications of the novelists who introduce lunatic asylums into their plots, and the tirades of half-cured lunatics, they are believed by those who know no better, and asylums are still looked upon by many as the homes of the blackest iniquities. The best way to counteract such erroneous notions is to throw asylums open to public inspection more and more, so that just ideas as to their organisation and discipline may be widely disseminated. And another way of creating sounder ideas than now prevail on asylum administration is by securing the delivery of lectures such as that which we have been noticing. Dr. Yellowlees' address proves that the Glasgow Asylum at any rate is presided over by a man of great ability and kindly sentiments. It breathes practical philanthropy throughout, and finishes with an earnest declaration that it is requisite for the highest health of the mind that man should have something outside himself to live for, and by, and that the fear of the Lord is not only the beginning of wisdom, but the essential condition

of that calm, trustful, and hopeful spirit which is the best safeguard against mental overthrow.

Notes on Current Topics.

Very Peculiar People.

THE sect of persons known as "Peculiar" People has suffered a blow by the committal on Friday last of one of their body on a charge of manslaughter. This victim of barbarian zeal is the father of a family, one of the members of which, a boy aged eight years, died of confluent small-pox, without any attempt having been made by the parents to procure medical aid on his behalf. At the inquest necessitated by the refusal of the authorities to grant a certificate of burial in the absence of medical testimony as to the cause of death, certain curious and instructive evidence was tendered by the witnesses called. Occasionally in the past the public conscience has been scandalised by outrageous contraventions of all ordinary sanitary regulations by individuals claiming to belong to the "elect," who in their supreme contempt for ordinary customs of civilised life have actively endeavoured to inflict disease and death on their surroundings. Thus, too, in the present instance, the wife of the accused man declared to the coroner that while her son was lying ill of confluent small-pox her husband and nephew were "out and about as usual," and in reply to the inquiry whether her creed authorised the murdering of a whole street full of people, she confidently replied, "there is no fear of that." In this simple confession there is surely enough to convince any unprejudiced observer that the miserable wretches who style themselves "Peculiar" deserve more justly to be entitled imbecile. Much as we may respect the trust and resignation that so distinctly mark the character of the truly devout and religious, there is something widely different from this in the behaviour of the ignorant fanatics who are now brought into conflict with "the world." Arrogance, ignorance, and idiocy are manifestly exhibited in the performances of the "Peculiar;" and with this the certainty that they are permitted to persist in their special observances at the critical expense of ordinary citizens, is the best proof of a necessity for their being compelled to conform, at least outwardly, to the usual rules of civilised existence. It is gratifying, therefore, to find that the unhappy child-victim's father is charged with the manslaughter of his son; and we may hope that ere long the Peculiar People will arrive at the conclusion that it is wiser and better to trust in medical skill to cure their sick and maimed than in the superstitious ceremony of "laying on of hands," however that may be associated with unlimited faith in extraneous powers.

Blind Opposition.

DISGUSTED as every sensible reader of the *Hull and Eastern Counties Herald* must be with its outrageous opposition to scientific evidence in support of criminal charges, they must still be unfeignedly amused at the utter stupidity displayed in an article which recently appeared in the

paper, commenting on the inquest held on the victim in the Wimbledon poisoning case. It was almost to be expected, however, that anti-vivisectionists would seize on the admission made by experts in respect to the mode in which these inquiries into the nature of the poison employed were made; and the sacrifice of the few insignificant animals involved in these proceedings has called forth a howl of execration from the *Hull and Eastern Counties Herald's* anti-science contributor. We cannot forbear to quote from the inimitably ignorant tirade of this writer the following imposing exhibition of fogged comprehension. It need only be added that the succeeding paragraph in the article quotes Dr. Mason Good to prove that "this great law in connection with the variability of gastric juice is a *direct protest against such unscientific experiments.*" The italics here and in the subjoined passage are our own. "By an universal and unerring law, every animal is provided with a differently-constituted apparatus for the assimilation of its aliment, and the fluids employed for digestion vary continually in the same species down to each individual type. *This point has not been overlooked by physiologists.*" To say that the brilliant writer of the article has been the first to appreciate that which he thus formulates, is unnecessary. Nor need it be said that such understanding omniscience is a common attribute of the anti-vivisectioning mind. Sickening cant and blasphemous nonsense are such strong weapons in the hands of non-scientific fanatics that we are not surprised to find it invoked, as usual, in this instance, and the following is a fair sample of the kind of argument employed in such connection: "The giver of all things has conferred on every creature down to the meanest organisation a relish for the kind of food best adapted to appease hunger and sustain life, and this inclination to select proper aliment is clearly to avoid whatever is hurtful. To feed defenceless animals therefore by stratagem or by force on substances foreign to their requirements, and calculated to induce painful sensations, is altogether repugnant and unjustifiable." This is on a par with the proceedings of a staunch upholder of anti-vivisection who recently was meted out well-deserved punishment for maltreating an animal in his possession, notwithstanding his assertion that he annually subscribed £20 to the Society that strives to impede the progress of knowledge in this country. It is impossible, of course, to inform such stupendous ignorance as is exhibited by persons of mental calibre like that shown by average anti-vivisectioners, but we may hope, by entering on a patient and determined crusade against prejudice and fanaticism, so to educate the public mind that it shall cease to pay heed to the empty vapourings of senseless bigots, while it hearkens to the voice of science declaring the utility of its own works.

MR. SPENCER WELLS, F.R.C.S., Vice-President of the Royal College of Surgeons of England, has been appointed to deliver the next annual Hunterian Oration at the College. Mr. Charles Hawkins, F.R.C.S., Government Inspector of Anatomical Schools, and a former member of the Council of the Royal College of Surgeons of England, has presented an interesting and valuable collection of surgical instruments to the Museum of the College.

Fashions in Therapeutics.

DR. J. W. HAYWARD, in an address on this subject, gives an instructive and entertaining account of the changes and theories by which the treatment of disease has from time to time been influenced. We do not purpose now to do more than allude to the address, hoping to give it more extended notice in a subsequent issue. We cannot, however, refrain from quoting the closing sentence, which is as follows: "The best preventive of all these fashions and habits is constant familiarity with the *Materia Medica* and *Repertory*; a constant appeal to the *Repertory* will do very much towards keeping us out of all fashions and habits." Who will not endorse this statement?

The Sale of Poisons.

No doubt public opinion is ripening as to the necessity for more restrictions in regard to the sale of poisons. Several of the leading newspapers in commenting on some of the facts brought forward in the trial of Dr. Lamson have expressed astonishment that a poison like aconitia should be obtainable by so simple a process as that of a signature by a person alleging himself to be on the Medical Register. The Coroner who presided over the investigation into this case made a comment to that effect during the inquiry on Tuesday week. Mr. St. John Wontner, who was engaged in the case on behalf of the Public Prosecutor, is reported to have said that the Act applying to the sale of poisons would no doubt be amended next session. This statement is of importance, as, no doubt, Mr. Wontner did not make that remark without sincerity. There are other indications that the subject is attracting attention.

Sham Doctors.

A MAN named George Middleton, who is described as a surgeon, has been sentenced to twelve months' imprisonment at the Plymouth Police Court for obtaining money under false pretences. His name does not appear in this year's "Medical Directory."

AGAIN, another man, named William Yelverton Davenport, also described as a surgeon, was convicted of perjury at the Central Criminal Court on Thursday, and was sentenced to twelve months' imprisonment with hard labour. We cannot find his name in the "Directory," so it is only fair to conclude that he also is not a qualified medical man. The *Students' Journal* very properly says: "It is most unjust to the profession that such fellows should be described as medical men in the daily papers, when they have no legal claim to the position. The profession has enough to contend with from its own black sheep without being obliged to father the misdeeds of every ruffian who has at some time or other had the honour of dispensing a bottle of medicine."

DR. CONWAY, in the *Virginia Medical Monthly*, reports a case of a boy who had been forced to inhale the "perfume" of the skunk by his school-fellows as a practical joke, and was rendered totally unconscious, with relaxation of the muscular system, for over an hour. A little whisky was given him and friction applied. When roused he suffered no inconvenient results except a slight headache.

Our Services to the Cause of Poor-law Medical Officers.

WE have received a pamphlet issued by the Poor-law Medical Officers' Association, setting forth the services rendered to Poor-law medical officers by a certain medical journal during the past year. A great many of the legitimate claims of contemporary medical journals has never been one of our failings, but we do think this special pleading, in favour of one journal, is not likely to advance the interests of the association, or to find favour with the bulk of Poor-law medical officers. Their sense of fairness will make them feel that their claims have not been neglected by the other medical journals; even gratitude, which has been defined as a sense of favours to come, will prompt some of them to admit that the action of the council of the Poor-law Medical Officers' Association has been in the highest degree impolitic. The association is wanting funds, subscribers are falling off; we do not now wonder at this. We do not insist upon our services to the Poor-law medical officers, or repeat the various annotations which have appeared in the *Medical Press and Circular* relative to their interests. The Irish Poor-law Medical Service appreciates our work. We have for years published a special supplement, giving news interesting to that important branch of the public service. The English service will continue to receive our support, in spite of this mistake on the part of the Association, a mistake, which, to some extent, seems to have been prompted by the egotism of one of the officials of the Poor-law Medical Officers' Association.

General Practitioners and the Medical Commission.

THE Medical Commission having concluded their sittings their report will appear in due time. Many eminent men have been examined—representatives of universities, colleges, societies, even herbalists. We have been struck by the fact that no one was examined who represented the views of the largest body of medical men in the country—the general practitioners. As Artemus Ward might have asked, we ask.—If not, why not? What can Sir W. Greatgun, or Sir Simeon High Science know about the requirements of this large class, of their grievances, or their ambitions. To work as a general practitioner is an education in itself. It is now too late to remedy this. But the general practitioners may learn a useful lesson. They are not organised as a body. If they had leaders they would have been to the fore, and they would have been officially represented. We shall be told they are organised. There is a grand body called the British Medical Association. They have a provincial journal, published in London. We venture to think that the provincial members of this high sounding Association are finding out that this journal is a Metropolitan one, and that the provinces play but a minor part in connection with it. They will have to look to other journals for support of their views, claims, and aspirations. There is a growing feeling in the country against this centralisation policy. The *Journal* does not befriend the provinces. Another subject of importance to the general practitioner is that of unqualified assistants, a proper subject for investigation by the Medical Commissioners. We have not

heard that any evidence was received on this point. There are, we believe, about 2,000 unqualified medical assistants. Surely, something must have been said for, or against, their employment. Evidence on both sides ought to have been submitted. Again, we say, the general practitioners have missed an opportunity.

Dublin Corporate Disinfection.

THE above heading does *not* mean that the Dublin Corporation has been disinfected, but refers to the arrangements for stamping out contagion, provided—or supposed to be provided—by the said body. We want to know whether it is true that the disinfecting chamber of the Dublin urban sanitary authority has been itself on the sick list, and incapable of transacting business for nearly a month, and that, during that period, the citizens have been obliged to nurse their contagion-laden clothing and bed-gear in any way they could? As corroboration of this rumour we note that, in the monthly report of the Medical Superintendent Officer of Health for the city, it is stated that, in the four weeks ending December 31st, the disinfecting chamber was used by *nine* persons only, which, considering that the city is in the middle of a measles epidemic, is incomprehensible.

We do not suppose that the Town Council can keep the chamber from going out of order, but we do imagine that greater expedition might have been used in the repairs, and that its restoration might, with energy, have been effected in a few days.

The Metropolitan Water Supply.

DR. FRANKLAND, F.R.S., issues a very sorry report of the London water supply during the past month. The water sent out by the West Middlesex and Southwark Companies for consumption by their customers, he tells us, was "much polluted with organic matter," while that of the Grand Junction and Lambeth Companies contained "moving organisms, and was of worse quality than any supplied since March last." We can quite bear out Dr. Frankland's statement, so far as the latter company's water is concerned, having had specimens of the water drawn from a cistern on the premises of a large employer of labour submitted to us for examination. We found that it abounded in circomonas and organic matters, animal and vegetable, prejudicial to health.

The extenuating plea so often put in for the companies by the water examiner, that the cistern of their consumers is the chief source of the contamination reported, had no existence, for the supply was on the constant system, and the specimens represented the actual condition of the water as supplied by the company to its customers. A sharp controversy has again taken place in the columns of the *Times* on the water supply of London, and we fail to see why it should as regularly subside, leaving the companies in undisturbed possession of their monopoly, and Londoners, their compulsory customers, doomed to buy and drink their dirty solution of "organic matter and moving organisms" for a further indefinite period, and at an increased rate, without any kind of redress.

Society of Medical Officers of Health, Dublin.

At the annual general meeting of the Society, which was held at the Royal College of Surgeons, on Wednesday, the 11th of January, 1882, a paper was read by Dr. Delahoyde, on "The Water Carriage System of Filth Removal: Is it Advisable that its General Adoption in Dublin should be made Compulsory?" Afterwards a discussion took place. Mr. Young, superintendent of city cleansing, was present also, who said that "he thought the trough closet applicable to houses containing a number of families and the ordinary water-closet suitable for small houses. There were erected in Dublin model water-closets and ashpits which cost about £12. These facilitated the removal of waste matter, but the cost was rather high for the smaller class of dwellings." The Society then proceeded to the election of officers, when the following members were elected to serve as officers of the Society for the year 1882:—President, Dr. Darby; Committee, Drs. Chapman, Delahoyde, C. F. Moore, Nowlan, Purcell, Speedy; Hon. Sec., Dr. Pollock; Hon. Treasurer, Dr. Cameron. It was moved by Dr. Chapman, and seconded by Dr. Darby, "That the best thanks be given to Dr. Cameron for the interest he has taken in the Society during the past two years while acting as president."

The annual dinner will take place on Saturday, the 21st inst., at 7 o'clock, at the Shelbourne Hotel.

Fallibility of Government Analysts.

A SIGNIFICANT case came recently before the Marylebone magistrates on November 30. It will be remembered that the Act provides, when the public analyst's decision is disputed, the part of the original sample shall be submitted to the Somerset House chemists, whose decisions were intended to be final.

Many disputed cases have been referred to the Somerset House chemists, but till the present no analyst has had the courage for an act which at first sight looks like tilting at a windmill.

In the case we have referred to Dr. Blyth certified that a sample of bread contained 4·7 grains of alum to the pound. The Somerset House authorities declared it "free from alum." Properly speaking, according to the Act, the case should have ended here with a verdict for the defendant, but the pertinacity of the prosecutor's solicitor persuaded the magistrate to allow Dr. Blyth to be heard in support of his certificate. Dr. Blyth stated that for some time he had made a special study of bread and flour analysis, and was able, by his improved processes, to detect the presence of alum in bread with greater accuracy and certainty than had ever been done before. The gentlemen at Somerset House might have used one of the older methods of analysis. The magistrate said that it was absurd to expect him to decide between such parties, and adjourned the case *sine die*; either party could bring it on again if they wished.

Laceration of the Cervix Uteri.

In the *New York Obstetrical Review*, Dr. Rohé, of Baltimore, relates two cases that have come under his observation, in which the occurrence of false labour-pains, of considerable severity, and persisting for a length of time before labour actually began, seemed to him to be due to the presence of laceration of the cervix. With a single exception, he remarks, authors make no mention of the relations between the two conditions. The exception noted is Goodell, who in his "Text-book of Gynæcology," relates a case in which pregnancy took place twice in a patient with lacerated cervix, and in which the labour was painful and difficult each time, the patient being confined to bed by her suffering for a month previous to the termination of the labour. The only other reference to the influence of lacerated cervix upon the course of labour, which he has found in literature, is confined to cases of dystocia due to cicatricial contraction of the cervix. This was not present in the two cases reported.

A Fortune in a Sauce.

MR. JUSTICE CHITTY had before him on December 21, at the Rolls Court, Lincoln's Inn, a motion on behalf of Messrs. Goodall, Backhouse & Co., druggists and dry-salters, of Leeds, to restrain Messrs. William Smith & Co., who carry on business as sauce and pickle manufacturers, at Morley, near Leeds, for infringing the plaintiffs' trade-mark, bearing the words "Yorkshire Relish." It was stated that the plaintiffs had been making the relish for more than seventeen years, had registered the trade-mark, and were now selling for the home market and for export about 5,000,000 bottles of it in the course of the year. There was no appearance on the part of the defendants, and his lordship granted an injunction.

The late Dr. Harvey, of Dublin.

THERE was a large attendance at a meeting of this gentleman's lay and professional friends held last week at the King and Queen's College of Physicians in Ireland, and summoned to consider the suggestion that a memorial to him should be established. In the absence of the President, the Vice-President of the College, Dr. J. W. Moore, was moved to the chair. Dr. Robert McDonnell, F.R.S., moved, and Mr. R. W. Boyle, J.P., seconded, the following resolution, which was unanimously agreed to: "That, in recognition of the eminent scientific ability of the late Dr. Reuben J. Harvey, and of his services to the advancement of the study of physiology, and to the improvement of medical education, a fund be now raised to establish a memorial to him." The appointment of a committee to carry out this object was moved by Dr. Banks, Regius Professor of Physic in the University of Dublin, and seconded by Dr. Cruise. The committee consists of the following gentleman, with power to add to their number:—Dr. Apjohn, Dr. Athill, Dr. Banks, Dr. Barton, Dr. Bennett, Mr. R. W. Boyle, J.P.; Dr. Corley, Dr. Cruise, Dr. C. E. Fitzgerald, Mr. G. F. Fitzgerald, F.T.C.D.; Dr. Gordon, Rev. Dr. Haughton, Dr. Kidd, Dr. James Little, Mr. Nicholas Lynch, Dr. Lyons, M.P., Dr. Robert McDonnell, Dr. MacDowel, Dr. J. W. Moore, Dr. Ormsby, Rev. Canon Travers Smith, B.D.; Professor

Gerald F. Yeo, with as Honorary Secretaries, Professor E. P. Wright, and Dr. C. J. Nixon. Other resolutions were proposed and seconded by Rev. Canon Travers Smith, B.D., Professor Thornley Soker, Dr. Apjohn, Jacob, Wharton, and Atkins. A subscription list was opened, and the sum of £100 was subscribed in the room. The Treasurers appointed are George F. Duffey, M.D., 30 Fitzwilliam Place, Dublin, and R. W. Boyle, J.P., 35 College Green, Dublin, to whom contributions to the fund may be sent.

At a meeting of the students of the Carmichael College on the 13th inst., it was unanimously decided to erect a tablet to his memory in the College. A subscription list was opened for that purpose. Mr. J. A. Scott being appointed treasurer, and Mr. S. D. Chandler, secretary.

At a recent meeting of the Council of the Medical Society of the College of Physicians in Ireland, the following resolution was unanimously adopted:—"That the Council of the Medical Society of the King and Queen's College of Physicians, Ireland, desire to place on record their profound regret at the death of Dr. Reuben Harvey, a Member of Council, and their sense of the loss which the Dublin School of Medicine has sustained by his demise, and that a copy of this resolution be submitted to the Honorary Secretary at the next meeting of the Society."

The Registrar General's Returns.

A NEW departure has been made this year in the publication of the vital statistics of large towns. Hitherto, only those having populations of over 100,000 inhabitants were included in the returns; henceforth, all those municipal boroughs in which the enumerated population in April last exceeded 70,000 persons will appear. The towns of Croydon, and of West Ham, though each has a population exceeding this limit, do not appear in the list, but are not really omitted from the return, as they form part of Greater London. Last week the rates of mortality in these towns per 1,000 of their population were—Halifax 13, Blackburn, Birkenhead, Huddersfield, 18, Edinburgh, 19, Derby, Bradford, Bristol, 20, Plymouth, Leicester, 21, Newcastle-on-Tyne, Sheffield, Sunderland, 22, Norwich, Birmingham, London, 24, Hull, Manchester, Portsmouth, Cardiff, 25, Glasgow, Oldham, Bolton, 26, Leeds, Wolverhampton, 27, Nottingham 28, Brighton 30, Salford, Liverpool, 31, Preston and Dublin, 36.

The highest death-rates per 1,000 from scarlet fever were 6.2 in Hull, 3.0 in Nottingham, and 2.4 in Brighton; from whooping-cough, 2.6 in Salford, 2.4 in Brighton, and 1.7 in Bradford; from measles, 5.3 in Preston, 2.6 in Leeds, 2.3 in Salford, and 1.8 in Liverpool; and from "fever," 1.4 in Plymouth, and 1.2 in Portsmouth. In Hull 19 more fatal cases of scarlet fever were recorded, raising the number recorded within this borough since the beginning of July to 661. The 49 deaths from diphtheria included 13 in London, 14 in Portsmouth, 12 in Glasgow, and 3 in Birmingham. Small-pox caused 22 more deaths last week in London and its suburban districts, one in Nottingham, one in Oldham, one in Bolton, and one in Leeds.

The Alleged Conspiracy at Sunderland.

THE trial of Dr. Abrath and Michael M'Mann, who stand committed upon charges of conspiracy to defraud the North-Eastern Railway Company, will take place at the Durham Assizes, which commence to-day (Wednesday), and is expected to occupy several days. We understand that Mr. Day, Q.C. (specially retained), will appear for Dr. Abrath, and Mr. C. R. M'Clymont will defend M'Mann. Mr. Digby Seymour, Q.C., Mr. Waddy, Q.C., and Mr. Walton will prosecute on behalf of the North-Eastern Railway Company. A good deal of evidence in favour of the defendants, which did not come out at the magisterial investigation, will be adduced before Judge Mathew and a special jury, when full justice is sure to be done in the case.

A WIDOW, named Hort, of Islington, died on December 26 from the effects of a bottle of whisky taken to destroy life. She was habitually temperate.

THE *Daily News* publishes the following from its Naples correspondent—The sudden departure of an Italian despatch boat Capera with several eminent physicians on board has raised great anxiety for Garibaldi's health.

As additional accommodation is urgently required at the Gloucester County Lunatic Asylum, it has been resolved to proceed at once with the erection of a new block, which will afford additional accommodation for about 300 beds.

We understand that the committee of the Religious Tract Society have just sent a parcel of Christmas and New Year's cards to hospitals and infirmaries in almost every county in the United Kingdom, and also to a large number of workhouses, asylums, and charitable institutions in London and the provinces.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 37, Bombay 29, Madras 39, Paris 33, Geneva 16, Brussels 22, Amsterdam 28, Rotterdam 23, The Hague 20, Copenhagen 25, Stockholm 19, Christiania 29, St. Petersburg 49, Berlin 24, Hamburg 25, Dresden 28, Breslau 32, Munich 31, Vienna 29, Prague 27, Naples 29, Turin 20, Alexandria 38, New York 29, Brooklyn 24, Philadelphia 20, Baltimore 27. No returns were received from Rome, Lisbon, Venice, or Buda-Pesth.

THE *Avenir de la Mayenne* reports the extraordinary fact of six persons, forming one family, suddenly going mad. This family, which lived at Andonille, Mayenne, is composed of Pierre Lochin, aged sixty-four; his wife, about the same age; two sons, and two daughters, whose ages range between thirty and twenty-four. All these persons are afflicted with the same hallucination. They believe that they have been poisoned by witches, and that the Devil has concealed himself in their clothes. These poor maniacs have just been taken to the Asylum of La Roche Gaudin; but for some time previously they are said to have prowled about the country during the night, in the scantiest of clothing.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

HEALTH OF EDINBURGH.—For the week ending with Saturday, the 7th inst., the death-rate of Edinburgh was 19 per 1,000, the deaths amounting to 83. There were only 5 zymotic deaths reported, none of which occurred in the southern suburbs.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 7th inst., were at the rate of 27 per 1,000 per annum, against 27 in the preceding week, and 31, 27, and 32 in the corresponding periods of 1831, 1880, and 1879.

GLASGOW HEALTH LECTURES.—In referring to this volume of lectures just published, our contemporary, the *Glasgow Herald*, very properly remarks, "We have one fault to find. We do not think that the lecture intended solely for, and delivered exclusively to, females, should have been printed in a volume intended for general circulation." This is exactly our contention, and we are glad to find so powerful an organ of lay opinion adopting the view so strongly urged in these columns.

MATRICULATION AT THE UNIVERSITY OF EDINBURGH.—The returns for the past year have now been made up, and again present a satisfactory increase. The aggregate number of students on the register and in residence during the past year was 3,237. The returns for the three previous years were as follow:—In 1878 the students in residence were 2,617; in 1879, 2,856; and in 1880, 3,172. The students are divided between the different faculties in the following proportions:—In the Faculty of Arts there are 1,047 students; in the Faculty of Divinity, 94; in the Faculty of Law, 458; and in the Faculty of Medicine, 1,638. The percentage composition is therefore—in Faculty of Arts, 32.3 per cent.; Faculty of Divinity, 3 per cent.; Faculty of Law, 14.2 per cent.; Faculty of Medicine, 50 per cent. The numbers and successful development of the Medical School is steadily kept up by the wide and increasing range of supply of students, to which India, our colonies, and even foreign countries, largely contribute. The entries in the register show that of the 1,638 students enrolled in the faculty, Scotland contributes 638, or about 39 per cent.; England 585, or 35.7 per cent.; Ireland 30, or 1.8 per cent. India 120, or 7.3 per cent.; the colonies, 202, or 12.3 per cent.; and foreign countries 63, or 3.8 per cent.

EDINBURGH UNIVERSITY—CHAIR OF GEOLOGY.—The Queen has been pleased to approve of the appointment of Mr. James Geikie to the Professorship of Geology and Mineralogy in the University of Edinburgh, on the resignation of Professor Archibald Geikie. The resignation of Professor Geikie will not, however, take effect till May, when he will have terminated his present course of lectures.

SIR ROBERT CHRISTISON.—We regret to say that Sir Robert Christison still remains in a very weak and prostrate condition, and little hopes are now entertained as to his ultimate recovery. Sir Robert was born in 1797, so that he is three years older than the present century. He was for fifty-five years a Professor in the University of Edinburgh, and it was only in 1877 that a severe attack of illness warned him to desist, and compelled him to seek renewed health in retirement.

THE CHAIR OF NATURAL HISTORY.—Pending the refusal or acceptance of this chair by Mr. Balfour, F.R.S., active

canvassing is still going on by the other candidates. Among these is Dr. Andrew Wilson, a lecturer on botany, zoology, and other kindred subjects, to most of the young ladies' schools of Edinburgh. It is fortunate for the University that a lady is not the Secretary of State, or Dr. Andrew Wilson might owe a professorship, as he does a doctorate, to the influence of the softer sex.

Correspondence.

THE ETHICS OF HOMŒOPATHY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your paper of this date, under the above heading, you say:—"The law of similars and the administration of infinitesimals have been publicly disclaimed officially in our columns by a Vice-President of the Homœopathic Society."

Will you permit me to say that, as this quotation must refer to myself, I must beg to state that you entirely misrepresent my views and statements?

I have always believed and written exactly contrary to the statements you attribute to me. In the Drs. Wyld and Richardson letter, which appeared in the *Times* and *Lancet* some years ago, and in my letter to your journal, my statements were these:—

"I believe, with Hippocrates, that some diseases are best treated by contraries and some by similars. I further believe that the law of similars is the most widely applicable of all the laws of healing. Lastly, I believe in the action of infinitesimals, although, if tangible doses of medicine are as effectual as infinitesimals, it may be, in deference to opinion, advisable to prefer the use of tangible doses."

Finally, I epitomised my views thus:—

"Medicine being a progressive art and science, it is competent for any legally-qualified medical practitioner to use any system he believes to be best for his patients. Nor should the adoption of any system of medicine exclude any legally-qualified practitioner from the first professional intercourse, provided he does not trade on a distinctive name, nor unprofessionally advertise his mode of practice."

Your obedient servant,

GEORGE WYLD, M.D.

12 Great Cumberland Place, Hyde Park,
11th Jan., 1882.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I do not know what foundation you have for your assertion that "the two essential peculiarities of Hahnemann's doctrine—the law of similars, and the administration of infinitesimals—have been publicly disclaimed officially in our own columns by the vice-president of the Homœopathic Society." You are probably not aware that the British Homœopathic Society elects one president and two vice-presidents every year, and that the vice-presidents only hold their office for one year. Moreover, neither the president nor vice-presidents have any authorisation from the Society to disclaim officially anything pertaining to homœopathy, far less the main principle of homœopathy—the law of similars—and if any former vice-president has done this, his act is purely *officious* and not *official* at all, and were he to do such a thing, he would thereby contravene the obligation he voluntarily incurs on being admitted a member of the Society, as he subscribes a formal obligation to "advance, to the utmost of his power, the doctrines and practice of homœopathy," and the "law of similars" is the very foundation of the doctrines and practice of homœopathy.

Moreover, so far from the "assumption or acceptance of a designation implying the adoption of a special mode of treatment" (to use the words of the resolution passed by the College of Physicians,) being part of the "Ethics of Homœopathy," the rules of the British Homœopathic Society, which is the only recognised arbiter of ethics among the practitioners of homœopathy, pronounces the penalty of expulsion against any member who shall announce or publish his mode of practice, and refuses to admit to its membership any person who

shall even announce on his door-plate or visiting card, his mode of practice.

It is utterly incorrect to accuse medical men who have studied, and who practise the homœopathic method in cases suitable for it, of "trading upon such designations." We have not assumed the designation of "homœopath;" and if we are so called by writers and speakers, we consider this to be done for the sake of brevity, and to avoid circumlocution, just as we speak collectively of the opponents of homœopathy as "allopaths;" but in no other sense do we or they accept these designations. We only acknowledge ourselves to be physicians and surgeons, graduates of this or that university, or members of this or that college. We cannot, nor do we wish to conceal that, as a rule, we practise the homœopathic method when we prescribe medicine; but the treatment of diseases includes many things besides prescribing drugs, and we are not behind our so-called orthodox colleagues in availing ourselves of all the other means and appliances which we consider useful for the cure of disease.

As the resolution of the College of Physicians was ostensibly aimed at those who have adopted Hahnemann's reform, it has completely missed its mark; for the resolution it passed with such wonderful unanimity is merely a paraphrase of the rule of the British Homœopathic Society above alluded to, without the penalty attached to breaking their rule by the latter body.

If the College had wished to pronounce a formal condemnation of homœopathy and its practitioners, they should have adopted Dr. Bucknill's amendment, which declared that "no competent medical man can honestly practise the so-called homœopathic system." But the adoption of this amendment, though it expressed what most of those present would have liked to say, would have been attended by some inconveniences; for it so happens that a considerable number of the licentiates and members of the College do "practise the so-called homœopathic system," and to imply that these gentlemen were not competent, would be to condemn themselves for admitting incompetent members; and to impugn their honesty whilst admitting their competence, might have brought the College itself into dangerous proximity with the law of libel. But as the fussy meeting of the College, like the mountain in labour, must bring forth something, they were fain to produce this ridiculous mouse, to wit, a resolution that passes entirely over our heads, and could only hit some of their own members, who, as so-called "specialists," trade upon designations "implying the adoption of special modes of treatment," such as aurists, oculists, obstetricians, electricians, Mont-Doreans, and the like.

As to the resolution being a denunciation of consultations with those who hold to the homœopathic therapeutic rule, I think you are mistaken in supposing it to be so, for though, no doubt, several of the speakers denounced such consultations, the proposer of the resolution must have felt that any such denunciation "is opposed to those principles of the freedom and dignity of the profession which should govern the relations of its members to each other and to the public;" as his resolution has it.

I fully agree with Sir W. Jenner when he says that such consultations could not be for the advantage of the patient. Like him, I profess that my wish and intention is "to do good to the patient," and I should not think I could do him any good, but only harm, by exchanging what I believe to be my better method for the worse method of a so-called orthodox consultant. So when I or my patients think it desirable to have a consultation, I always call in one who is conversant with what I consider the better method. For purposes of diagnosis, or an opinion as to the advisability of a change of climate, or other hygienic measures, I do not see why physicians who practise different systems of therapeutics should not meet, but I cannot say that my attempts to get consultations with the representatives of orthodoxy on such matters, have been very encouraging. Probably, they entertain different ideas of the "principles of the freedom and dignity of the profession which should govern," &c., to what I do.

I have never found any difficulty in obtaining the co-operation of eminent surgeons when surgical aid was required, until a few months ago, when Mr. Lister suddenly refused professional intercourse with me in the case of a patient with a dislocated arm, to whom I had called him in.

Surely, Sir, our practice is not so "unscientific" as you endeavour to persuade your readers that it is, or your side, which you, of course, consider the scientific one, would not borrow so extensively from ours. I need only mention a few of your borrowings:—Aconite in inflammatory fever (Ringer); belladonna in erysipelas (Liston); inflammatory sore throat

(Ringer); ipecacuanha in vomiting (Ringer); corrosive sublimate in dysentery (Ringer); drosera in whooping-cough (Murrell). I could mention dozens more, but I will only add the latest specimen from the current number of the *Practitioner*:—sulphide of calcium in strumous ophthalmia (Snell). All these remedies for these diseases have been in constant use by our side for the last fifty years at least, but have only lately been discovered (?) by your side. You say that we have given up the practice, and only retain the name of homœopathy; to me it appears that your side have adopted the practice while dropping the name of homœopathy, for, with the exception of Liston, none of the above-named practitioners have acknowledged the source of their remedies. They have smuggled our property into their camp, taking care to efface the "homœopathic label." When our side resort to a non-homœopathic remedy, we do so openly and avowedly, and I may say regretfully, as that is an acknowledgment that we do not know a homœopathic remedy for that particular case. When your side "convey" homœopathic remedies into their practice they carefully conceal their origin, and make believe that their treatment is strictly orthodox, and the outcome of pure science.

I am, yours, &c.,

53 Montagu Square,
12th Jan., 1882.

R. E. DUDGEON, M.D.

"THE DENTAL DIPLOMA TRADE."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The trenchant observations made in your last issue on this subject deserve the most serious consideration, not only from the Royal College of Surgeons of Ireland and other licensing bodies, but also from every member of repute in the dental profession.

These observations will, I hope, rouse so much attention to the matter as may stave off dangers that, in the present state of things, threaten not only the dental profession as such, but also the very reputation of the College itself.

I do not attach so much importance to the rescinding of the rule laid down by the College—namely, that after October, 1881, no dentist should be admitted to examination who did not go through the regular curriculum. For there are, I am aware, many respectable men who were in the practice of dentistry long antecedent to the passing of the Act, who, from one cause or another, were prevented from taking advantage of the two years' grace, though it may have been their desire to have done so. That such should now be compelled to fall back upon the curriculum, after a long day of practice, as the only means of obtaining the *imprimature* of the College, might be considered harsh, if not unjust.

I think little of the relaxation of the rule when it is designed to meet in a professional and friendly spirit the wishes of these persons, if in the obtainment of the College diploma neither its reputation nor the efficiency and reputation of the profession suffer. But if it be rescinded and the doors of the College kept open for an indefinite period, other than the means hitherto adopted must be resorted to in order to prevent unworthy applicants from admission to examination.

I have studied carefully the *modus operandi* by which admission has been obtained, and I am fully convinced that it is, and must ever be, defective, especially so in regard to the dental profession, which is only yet in a state of transition.

The recommendation of two surgeons and two dentists of repute—the rule at present in operation—must be in many cases a deceptive passport. Such introductions have been, and can be, obtained from both surgeons and dentists by many persons who have no claim, by practice or otherwise, to admittance to the examinations.

A glaring instance of this kind occurred at one of the examinations. A person presented himself armed with the necessary forms, went in and passed, and I found after, as I suspected at the time, that this person was no other than a notorious quack doctor, which quackery he continued to practise until he was positively criminated.

Taking this view, I venture to think that continuing the examinations cannot fairly be objected to, but proper precautions and stringent measures are absolutely necessary to ensure eligibility of candidates. To discontinue the examinations would simply mean to drive candidates from Dublin to Edinburgh or Glasgow. This would certainly be no advantage to the candidates or the public; and it would be as certainly a disadvantage to our distinguished Irish institution.

The great drawback, then, as I see it, is not in the con-

tinuance of the examinations beyond the period originally set down, but in the mode by which candidates are admitted.

How then, it may be asked, should they be admitted? Not on the recommendations of doctors or dentists, but, as I would venture to point out, on the official authority of some recognised association or body interested in the dignity and well-being of the profession, and therefore bound to inquire into the antecedents of the persons before recommending them.

You, Sir, in your pointed comment, hint, I apprehend, at the adoption of some such course. You say, "The British Dental Association is able to take care of itself, and we have confidence that it will do so." Taking care of itself means, I believe, taking care of the interests of the profession; and when I mention that the Association is formed on the same lines as the British Medical Association, I think that there could be no better medium for recommending suitable persons to the College.

Hoping that the *Medical Press and Circular* will not lose sight of this important question,

I remain, Sir, yours faithfully,

JOHN O'DUFFY, L.D.S.R.C.S.I.

58 Rutland Square West, Dublin,
Jan. 12th, 1882.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—There is a statement made in an article under the above heading in your issue of the 11th inst., which I cannot allow to pass unnoticed, and which I trust, with your accustomed fairness, you will allow me to contradict. The writer states "at present the Colleges of Surgeons of Edinburgh and Dublin, and the Faculty of Physicians of Glasgow are doing a roaring business in dental diplomas." Now, sir, so far as the College of Surgeons of Edinburgh is concerned, the above statement is simply not true, as I proceed to show. Since the institution of the dental diploma in 1879, the number of diplomas granted are as follows:—1879, 14, 1880, 4, 1881, 19, which numbers do not certainly show a roaring business. I am far from inclined to defend all the acts of the College, or support the method by which examiners elect themselves year after year, but I can honestly say that a more competent board of examiners in Dental Surgery there does not exist, and although under certain regulations some students are admitted to examination *sine curriculo*, I know as a fact, that there is no modification of the examination to suit them.

I am, yours, &c.,

H. AUBREY HUSBAND.

Edinburgh, 11th Jan., 1882.

ALCOHOLIC CONVULSIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR—Your Northern correspondent in the current number of the *Medical Press* quotes part of the report of my evidence in the case of the recent trial for murder in this city, and invites me to give a fuller account of my views on the subject of alcoholic convulsions. Let me say in the first instance, that the words quoted were for the most part not mine, but those of the Crown counsel, who used them in the form of a question which was put to me. As reported, the exact significance of my reply is not conveyed.

With respect to the convulsions, or epilepsy as it is commonly called, due to the intemperate use of alcohol, two forms are to be clearly distinguished from each other. There is first, epileptiform fits which result directly from a recent debauch, and occur at no other time. This is the kind to which the wretched man referred to was subject; on several occasions he had severe convulsive seizures, but they all occurred after, even to him, excessive indulgence in drink. Then there is the form which is not infrequently met with in chronic alcoholism; the fits may happen when the individual is not taking more than his usual potations, and also when he has been abstaining entirely for a time.

Though the two kinds of fits are not to be distinguished by the phenomena of the seizures, and are both due to the same agent, they are really essentially different. The former, those directly induced by recent excess, are the immediate product of the circulation in the brain of blood poisoned by alcohol, and are analogous to the convulsions of renal disease; both being caused by a toxic agent in the blood at the time o

their occurrence. The latter class, those that arise during comparative or complete abstinence from alcohol, are the fruit of actual disease in the brain; a habit of system no doubt originally springing from, but now independent of, the toxic cause has been established; the fits are no longer epileptiform, they are epileptic.

In these remarks I have confined myself strictly to the relation of the alcohol to the seizures, and have refrained from referring to the influence of other causes in their induction.

Yours, &c.,

ALEX. ROBERTSON, M.D.

Towns Hospital and Asylum, Glasgow,
12th January, 1882.

COTTAGE HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am dispensary medical officer to a large country district. There is no hospital within reasonable distance, and a resident gentleman would like to assist in getting up a cottage hospital. Will you please allow me to ask, through your paper, for some practical hints in the starting of such an institution, or the experience of any one connected with such in this country?

Yours, &c.,

W. F. S.

THE CARBOLIC CRAZE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In reference to your note on the above subject, may I venture to refer to a case which recently occurred in my practice, and of which I fail to see any other explanation, than by attributing the most beneficial effects to "Listerian" dressings.

The patient, a lady, is over 80 years of age. She had a large ulcer, larger than a man's hand, on her right leg. This ulcer, when I first saw her, she had had for nearly three years in spite of assiduous care and attention. Dressings of every imaginable kind had been employed; lotions of carbolic acid very largely. At the time I saw it, the ulcer was very deep, with hard gangrenous-looking edges, and was covered with a mass of fungus and decayed granulations that gave it all the appearance of being a surface of green pile velvet. For six months longer every dressing I could think of had a fair trial. The fungus was cauterised down. Iodoform, carbolic acid, chloride of zinc lotion, permanganate of potash, iodine, and pressure, were all tried in turn, with no result. The ulcer was as large as ever, as painful as ever, and as foul as ever. On the 18th of July last I dressed it for the first time by Lister's method, under the spray. It was subsequently dressed eight times in the same way, and on the 8th of August I had the satisfaction of seeing a clean, healthy granulating sore, and the satisfactory line of advancing epidermal tissue. Having once got the sore into a thoroughly healthy condition, which two and a half years of assiduous treatment by other means had failed to do, I resorted once more to the use of simple carbolic lotion to wash the sore within, and a dressing of sulphate of zinc lotion. The middle of last month saw the ulcer healed to the size of my thumb-nail, all pain and discomfort gone, and the old lady better in health than she had been for years past. Unfortunately, other mischief set in, and she now lies seriously ill again, but from a totally different cause.

My reason in writing this is to ask, if Lister's dressings are so useless, what is the explanation of the obstinate resistance of this ulcer to all attention and treatment, and of its rapid purification and amendment under a few Listerian dressings?

Yours, &c.,

Kineton, Warwick.

KENNETH W. MILLICAN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Although I may be set down as one of those "incapable of forming correct judgment," yet I must protest against the paragraph in your number of Jan. 3, 1882. "Carthago est delenda," insulting as it is to the many humble practitioners like myself who have, from time to time, furnished short articles, illustrative of their experience in antiseptic surgery, accusing us of being influenced by a desire of "a chance of advertising."

I will not defend myself further than to say, that in any statement I ever made on the subject, I had no object but that of inducing others to inquire, and having inquired, to practice what I believe to be one of the greatest advances made in practical surgery during the current century. Any fair-minded man who has visited Mr. Lister's *clinique*, must be convinced also, that he is perfectly earnest and honest in all he says and does, and I do not envy the man who can be led to throw suspicion on his motives.

As to the utility of his mode of practice, I remember a young surgeon, now amongst the leading men of Dublin, making to me, at the Leeds meeting of the British Medical Association, remarks similar in bearing to those in your journal which I object to. Time has made him one of the most earnest in supporting and successful in carrying out Mr. Lister's principles and practice.

I hear similar remarks made by men who have never seen the measures advised by Mr. Lister put in practice, and I have often been amused at the practice of others, who applying a loose piece of lint dipped in carbolised oil to a wound expect the same success as follows the complete manipulation of the true antiseptic surgeon; but, the real cause of all this is, that which too often leads even those convinced of the truth of the principle, to neglect them, viz., the extra trouble involved in carrying out the process.

At all events we are not where we were before this "carbolic craze," became the fashion. It is a mistake to think and say, that Mr. Lister confines his ideas to carbolic acid—his principle is antisepticism. He finds the use of carbolic acid the most convenient method of carrying it out, he ties no man to his mode of action, and I am persuaded that the great success following in the practice of those hospitals where Listerism is repudiated, is due to improvements which are corollaries or deductions from what the great antiseptic surgeon has taught, even though it be only cleanliness and ventilation.

Your obedient servant,

JAMES MARTIN.

Wood View, Portlaw.

INTERNATIONAL MEDICAL CONGRESS.

ACTING under the powers delegated to them at the final meeting of the Congress, the executive committee of the late Congress have addressed an invitation to Professors Hannover and Panum, Vice-Presidents of the Congress, to arrange for holding the next International Congress in 1884 at Copenhagen. This invitation has been promptly and cordially accepted, and the next International Congress will accordingly be held in the year 1884, in Copenhagen.

DR. QUINLAN, Physician to St. Vincent's Hospital, Dublin, has been appointed Consulting Physician to the Dublin Dental Hospital.

By an oversight which we regret, the name of Dr. P. S. Abraham, Curator of the Museums of the Royal College of Surgeons in Ireland, was omitted from the list of candidates for the Professorship of Practical Anatomy in the College, published by us last week.

THE Registrar-General for Ireland announces that in accordance with advances which have taken place in medical science and nomenclature, it has become necessary slightly to modify the classification hitherto in use for statistical purposes. This modification will not materially alter the relation of the various groups of diseases to one another, and for all practical purposes the numbers tabulated under the new system are fairly comparable with those included under similar denominations in the classification of Dr. Farr, hitherto made use of in the returns published by the General Register Office.

UNIVERSITY OF ABERDEEN.—CHAIR OF PATHOLOGY.

OWING to the munificent gift (£10,000) of Sir Erasmus Wilson, a want long felt in the University of Aberdeen has been supplied, and the medical school may be said to be now complete. The University of Aberdeen has of late been showing signs of great vitality. We, therefore, congratulate the University on this addition to its strength. All that now remains is to select a competent man to fill the new chair.

THE HEALTH OF DUBLIN.

ACCORDING to the report just issued by Dr. Charles A. Cameron, Superintendent Medical Officer of Health for Dublin, the death-rate within the Dublin registration area (population 348,525) during the four weeks ending the 31st December was 33·47 per 1,000 persons living.

The rate within the City (population, 249,486) was 37·75 per 1,000.

The rate from the seven principle zymotics, in the whole district, was 4·85 per 1,000. In the city the rate was 6·3.

The admissions of patients affected with typhus fever showed a great falling off, as compared with preceding months. The admissions of typhoid fever patients increased slightly, and the admissions of persons affected with scarlet fever decreased largely, as compared with the preceding month. There was a very large increase in the admissions of children suffering from measles.

The high death-rate of December was caused nearly altogether by two causes—an epidemic of measles, and a large number of cases of bronchitis. Out of the total of 120 deaths caused by the seven principal zymotic diseases, no fewer than 101 were the result of measles. 28 children died from this malady in the North Dublin Union. Every effort has been made to arrest the spread of the epidemic; so far as it was possible the patients were removed to hospital, and the rooms which they inhabited were disinfected and thoroughly cleansed. When the patients slept upon straw beds or mattresses, these latter were burned at the Corporation disinfecting place, and replaced by new ones. This high morality from diseases of the respiratory organs was no doubt due to the very low temperature of a portion of the month. A serious outbreak of typhoid fever occurred in the Kildare Place Training Schools, which on investigation, I found was due partly to extremely defective sewerage arrangements, but chiefly to the use of drinking water from a cistern which was contaminated with sewage emanations.

Literature.

SOME RECENT WORKS ON CHEMISTRY.

(1) "A Dictionary of Chemistry and the Allied Branches of other Sciences." By Henry Watts, B.A., F.R.S., F.C.S., Editor of the *Journal of the Chemical Society*, assisted by eminent contributors. Third Supplement. Part II. London: Longman and Co.

(2) "Elements of Chemistry, Theoretical and Practical." By W. A. Miller, M.D., D.C.L., LL.D. Revised, and in

great part re-written, by Henry E. Armstrong, Ph.D., F.R.S., Sec. Chem. Soc., and Charles E. Groves, F.C.S., Sec. Inst. Chem. Part 3. "Chemistry of Carbon Compounds or Organic Chemistry." Section 1. Fifth Edition. London: Longman and Co.

(3) "Adolph Strecker's Short Text-book of Organic Chemistry." By Dr. Johannes Wialeceus, Professor of Chemistry in the University of Würzburg. Translated and Edited with extensive additions by W. R. Hodgkinson, Ph.D., and A. J. Greenaway, F.I.C. London: Kegan, Paul and Co.

(4) "A Treatise on Chemistry." By H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S., Professors of Chemistry in the Victoria University, Owens College, Manchester. Vol 3. "Organic Chemistry." Part 1. London: Macmillan and Co.

(5) "Annals of Chemical Medicine, including the application of Chemistry to Physiology, Therapeutics, Pharmacy, Toxicology, and Hygiene." Vol 2. By J. L. W. Thudichum, M.D. London: Longman and Co. 1881.

(1) To Mr. Watts, more than any other English scientific writer, the thanks of students of chemistry are due for valuable contributions to chemical literature. The chief work of his life, however, is undoubtedly the great Dictionary of Chemistry which bears his name. It is close upon twenty years since this work was commenced, and now we have to chronicle the appearance of the final supplement. This volume, of large 8vo. size, and more than 2,000 pages, completes the record of chemical discovery down to the end of 1878, including the more important discoveries of 1879 and 1880. The work on the whole is a most admirable compilation, and contains, besides, original articles of great value. If Mr. Watts proposes to abandon it now, we trust it is because he fancies that he can, with the aid of the able staff of abstractors of the Chemical Society, render their *Journal*, which he edits, an efficient substitute. Should Mr. Watts still possess the will to undertake such a task, there is no similar undertaking which would do so much service to science, as a thorough re-editing of this vast work, so as to incorporate the appendices into the body of the work, and render the whole a just representative of modern chemistry. Failing this, an index to the original work and its four volumes of supplements would be exceedingly useful.

Although the chief responsibility in carrying out this work falls upon Mr. Watts, we find that he has received assistance from a few scientific friends who have contributed monographs. Thus Professor G. C. Foster has written an essay, bristling with mathematical formulae, upon Thermodynamics. Professor Thorpe, of Leeds, furnishes a most valuable memoir on specific volume, embodying the researches for which was recently awarded the Longstaff medal of the Chemical Society as the best research during the previous five years. Mr. Warrington, the conscientious experimenter at Mr. Lawes's experimental farm at Rothamsted, shows in his article on Nitrification how there is reason to believe that the formation of nitrates and nitrites in the soil is but one more of the many natural processes in which the active agents are really minute organisms or "germs" (in this instance, apparently one that falls within Cohn's definition of a *micrococcus*).

In spectroscopic analysis much interesting work has been done. Captain Abney has opened a new field by his discovery of the possibility of photographing the ultra-red of the spectrum, whilst simultaneously, Professors Hartley and Huntingdon, by photographs in the ultra-violet, have shown how the composition of organic liquids may be ascertained by their absorption spectra. Higgins, Vogel, and Draper continue to work with success on the visible parts of the spectrum; and Messrs. Liveing and Dewar, having also turned their attention in this direction, have come somewhat into conflict with Mr. Lockyer, whose bold speculations are still inadequately supported by experiment.

Although the work abounds in novel facts, much that is given in this supplement may appear trivial to such as cannot see the purpose underlying their investigation; but it is astonishing how valuable these meaningless discoveries become when the key is known. It requires a special education to understand the researches which Professor Baeyer, of Munich, has published during several years past, yet anyone can estimate their importance now he has succeeded, by the knowledge thus gained, in making indigo artificially from coal-tar products, at such a price, too, that for some purposes it can compete with the natural dye. There are hundreds of other problems of importance that

are gradually solving themselves as facts accumulate; and chemists and science generally are deeply indebted to men like Mr. Watts, by whom the necessary materials are brought together.

Organic Chemistry, although a branch of the science which has made more progress than any other, is not the most studied in this country. Hence, where the difficulties are greatest, the incentives to writing a thorough work are least. Simultaneously, however, several chemists have been working to supply this need, and as a result, not one only, but three good works on Organic Chemistry have been recently issued. We have not space to review these important works with the completeness their merits deserve, but the following brief summaries will indicate their chief peculiarities:—

(2) The new edition of the Third Volume of Miller's "Elements of Chemistry," on "Organic Chemistry," is prepared by Professor Armstrong and Mr. C. E. Groves. The opening chapters are reproduced with scarcely a modification from the last edition, and thus compare but poorly with the corresponding pages of the works mentioned below, which introduce recent material. In the succeeding chapters we get ably written original matter, but it bears evidence of the time it has been in hand. In the latter half of the work, however, the facts are, on the whole, accurate and recent, and the theories skilfully handled. In the present volume, the hydrocarbons, alcohols, ethers, aldehydes, paraffinoid acids are treated of. In the next volume, the works will be completed—a consummation which, it is to be hoped, will not be long delayed.

(3) The Strecker-Wieslecken "Organic Chemistry" is a well-known German work, which Messrs. Hodgkinson and Greenaway have translated and edited. There is somewhat of a Teutonic flavour about some of the English in this book, but the information itself is trustworthy, and just such as the working student will require. It is expressed, too, in a terse way, which admits of a good deal being condensed into a short space. The work treats only of "pure science." The practical applications are scarcely, if at all, alluded to. It is complete in one volume, and therefore by no means so large as the works with which we are comparing it; considering, however, that it consists of nearly eight hundred large pages, it seems a somewhat of a misnomer to retain the title of "Small Text Book," which distinguished the original work of Professor Strecker.

(4) Roscoe and Schorlemmer's "Organic Chemistry" far outstrips all competitors in the costly way it has been brought out. The book is printed in large type, and on excellent paper, and is illustrated by numerous well-out wood engravings. This work is also distinguished from those previously mentioned by the fact that names and references are introduced on every available occasion, so that the treatise not only records the present state of our knowledge, but gives also an historical account of how that knowledge has been acquired. Another characteristic is the amount of attention paid to the details of "applied" organic chemistry. This scheme renders the work so bulky that only the hydrocarbons and their derivatives are discussed in this volume, and two others at least will be required to complete the undertaking.

(5) Dr. Thudichum's "Annals of Chemical Medicine," vol. 2, contains, like its predecessor, accounts reproduced *in extenso* of the Editor's own researches—consisting of papers on the non-phosphorised groups of nitrogenised principles of the brain; anaesthesia by volatile alkaloids, as illustrated by opium smoking; the isomers of cholic acid of the ox; besides summaries of the investigations of other workers upon the subjects mentioned in the title of the book. These summaries are perhaps more attractive than the uncondensed papers, for they bring together, in comparison, the work of observers, many of them continental, whose publications would otherwise be beyond the range of many of our readers.

There are, in all, twenty-two subjects touched on, many of which are of considerable value. We think, however, that the Editor would have better exercised his discretion by omitting altogether from his work the article entitled "On modern text-books as impediments to the progress of animal chemistry (a deduction)." The only books therein alluded to are Mr. Kingzett's "Animal Chemistry," and Dr. Gamgee's "Chemical Physiology of the Animal Body," and the elaborate onslaught on Dr. Gamgee's work renders it but too evident which way the writer desires the "deduction" to

be drawn. The whole article appears to us quite out of place in a work like this, especially when one considers how many facts of value might have been recorded in the same space.

The existence in the brain of a definite principle called "protagon" by Liebreich has been confirmed by Drs. Gamgee and Blankinhorn, and denied by Dr. Thudichum with equal confidence. Believing that "even the proposers and backers of 'protagon' themselves are reluctantly constrained by this time to look upon it as an exploded fallacy," Dr. Thudichum says in his preface he "feels no longer called upon to participate in any further discussion on this matter." Nevertheless, he permits reference to "a kind of chemico-theoretical 'super' on the physiological stage, viz., 'protagon,' to be made in the article above mentioned.

Dr. Thudichum refers to the estimation of sugar in two interesting articles, one treating on its estimation by the polariscope, the other by the "cupric test." In the latter, he says, after quoting one of Dr. Pavy's experiments. "This behaviour would show that, if in Bernard's experiments ammonia had any share, all the results of this author obtained by the method indicated are affected by a considerable quantitative error. But, as already stated, the solution of ammonia in Bernard's process is not yet proved."

In the above statements the Editor, we fancy, entirely misapprehends Dr. Pavy's position. This gentleman has already demonstrated by experiment the inaccuracy of Bernard's process; and this fact holds good whether he can or cannot prove his assertion that it is generated ammonia, and not organic matter, that holds in solution the suboxide formed by the reduction of the cupric tartrate.

Considering the difficulties medical men experience in following the modern chemical nomenclature which meets with general acceptance among chemists, we think it a pity the Editor should have further embarrassed his readers by words like "chemolysis," "quantation," "molecule" (for molecule), and so forth.

From what we have said it will be gathered that all the works we have mentioned are meritorious productions, and their comparative value will depend on the requirements of the reader.

Literary Notes and Gossip.

THERE have been but few changes in the medical journals of this country during the past year. The four old-established weeklies still maintain their position. Of new journals, one, the *Specialist*, did not long survive its birth, ceasing with the old year. Considering the small field at his disposal, the editor, Dr. Junius Hardwicke, of Sheffield, strove well and ably at his uphill task, but failed, as we predicted, for lack of adequate support, and a broader field. Another new journal, the *Medical News*, was started towards the end of last year, and is still in existence. These are the only journalistic changes at home to chronicle for 1882.

OF 1882 it is of course too early to speak, but if the present affords in any way an index of what is to follow, the year will indeed be prolific in journalistic ventures. First, we come to the *Students' Journal and Hospital Gazette*. After nine years existence as a fortnightly, the editor states that, "Owing to the increased number of medical students, and the demands made upon its space for matter of interest to that body, it has been decided to issue the journal weekly instead of fortnightly, and to reduce its price one half, from fourpence to twopence." This is one reason for the alteration, but we imagine the more cogent factor was the starting of another student's organ, and the editor and publishers of the original journal were determined not to be beaten on their own ground. Whatever be the cause, the *Students' Journal* has proved a valuable medium of intercommunication, and an aid to the student in times past, and we cordially wish it success in its new departure.

ANOTHER new feature in journalism is the starting this month of the *Midland Medical Miscellany*, by Messrs. Richardson and Co., the well-known manufacturing chemists of Leicester. For workmanship and general appearance this new monthly leaves nothing to be desired. But it does not seriously appeal to the profession for support, nor to us for criticism; it is a trade organ composed of fifty-two pages of

he advertisements and price lists of the firm, with sixteen pages of literary matter, and a portrait and biography of Dr. Janford Thomas. Having so recently (January 4th) expressed our views on the subject of "contemporary biography," we can hardly be expected to approve of this department of the new publication. On the other hand, when the editor essays "therapeutic notes" and gleanings from the medical and scientific journals, he is on genial ground, and has exercised considerable acumen in his selections.

BESIDE the journals before mentioned, the *American Journal of Obstetrics* starts a monthly supplement in order to bridge over the period between its regularly quarterly issues. This journal is in great demand on the other side of the Atlantic, and we doubt not will be favourably received in this country, now that English editorial and publishing co-operation has been secured. Three other new medical journals have also come to hand—all from America. The *Colorado Medical Journal*, a monthly, edited by Dr. W. H. Warn. The *New England Medical Monthly*, edited by Dr. W. C. Wile, and the *North Western Lancet*, a semi-monthly, edited by Dr. Jay Owens. These initiatory numbers seem well up to date, and contain much interesting matter; but in declining to increase our already over large "Exchange List," we beg our editors will not take it as a want of courtesy, but want of opportunity, to scan more than forty-two journals.

THE Neapolitan Medical School has, of late years, made great progress. It was well represented in London at the Congress. A *vide mecum* of the work of the school by Prof. Franco is announced, which will not fail to interest all who have visited the lovely city of the south, or have watched the progress of science in the University. A clinical journal has been successfully carried on during the last four years, and the *International Medical Journal*, published at Naples, has been conducted with great ability.

ITALIAN medical literature has lately been enriched by numerous translations of standard works from English and German; but original memoirs are also rapidly accumulating. Prof. Lemmola's works, as also those of Corradi, Palladino, Cantini, Palasciano, Caselli, Tomaselli, Paochiotti, and others are well-known to a number of their English confreres. Dr. Novaro has published at Turin his case of extirpation of the larynx. Dr. Cozzolino has, in the press, a monograph on *Ozæna*.

ALTHOUGH a preliminary education is now essential, and, in all cases, comprises Latin, "The Latin Grammar of Pharmacy," by Joseph Ince, F.C.S. (Baillière, Tindall, and Cox), will be found useful to many medical students, for it brings together, in a small compass, the rules which should be observed in writing, and, of course, in construing prescriptions. It gives *seriatim* the parts of speech, illustrating each by examples taken from words constantly occurring in prescriptions. A short syntax follows, with suggestions for reading prescriptions, tables of abbreviations, and a copious vocabulary. We have so often seen students non-plussed by the little peculiarities of medical latin that we are sure Mr. Ince's grammar will obtain a ready sale.

AT the meeting of the Council of the Royal College of Surgeons of England on Thursday last, five dissertations on "The Pathology and Surgical Treatment of Diseases of the Hip-joint" were received in competition for the Jacksonian Prize. These will, of course, have to be considered by a committee in the usual way before any award is made. At the same meeting it was also decided to print the second part of the catalogue of Osteology of the Vertebrata.

FOUR volumes, containing the papers read, and the discussions held, at meetings of the late International Medical Congress, have been issued within the last few days, and form an enduring memorial of the greatest meeting of the profession ever witnessed. The work in its completed form is an imposing and invaluable collection of monographs and speeches, and he influence it will exert on the future progress of science is difficult to estimate.

A BOOK which has passed so rapidly into a second edition as has Dr. Farquharson's "Guide to Therapeutics" (Smith, Elder, and Co.), hardly requires detailed criticism. This book is now well-known to students and practitioners, and

deserves the success it has met with. It has been thoroughly revised and brought up to a level with the most recent therapeutical knowledge.

"A TREATISE on Salt" (Baillière, Tindall, and Cox), is a novelty. Dr. Boddy has certainly opened out an unexplored mine, so that we have a thoroughly original piece of work treated in a pleasant, interesting, readable, but scientific manner, so as to fit it not only for the medical, but the general reader. The importance of salt is generally recognised, but few have thought it played such a wide part in the economy of nature. We have pleasure in recommending Dr. Boddy's little work to our readers.

WE have before us a numerous array of almanacs for 1882, from the three-foot placard for the wall, to the tiny time-reminder for the vest pocket; but the only one of special medical interest amongst them is Richards' Medical Almanac, which the author styles an "Epitome of Medicine." A quotation from this novel little publication will suffice to explain its contents. Thus: "August 1, 1602, Harvey became a Doctor of Medicine. He expounded the circulation of the blood, 1616. In 1628 he published his discovery. He died in London, 1657."

A REAL novelty in magazine literature has this year been introduced in *Cassell's Magazine*, under the title of the "Family Parliament." The discussions are exciting the liveliest interest, and a new debate, we see, is to be opened in the February number on the question, "Are Early Marriages Unthrifty?" The debates are open to all readers of *Cassell's Magazine*.

AN unfortunate controversy regarding literary work is now going on in the columns of the *Lancet*, between Dr. Cassells, of Glasgow, and Mr. W. B. Hemming, of Notting Hill. It is well known that Professor Politzer, of Vienna, has been, for some time past, engaged on an exhaustive work on the ear, and as there were many candidates for permission to make an English translation, Politzer yielded to the request of a former pupil, Dr. Cassells. Thereupon the late Mr. Douglas Hemming (whose obituary we published on Dec. 14th), an excellent German scholar, proffered his services to assist in the translation, and an arrangement was, we understand, made between him and Dr. Cassells. Subsequently Dr. Cassells elected to do the whole translation himself, and returned Mr. Hemming his portion of the work. We cannot, therefore, but think that it is a somewhat ungracious act on the part of Dr. Cassells to question the accuracy of a paragraph in an obituary notice, after accepting the assistance of the deceased gentleman, even though he did not make use of work which Mr. Douglas Hemming undoubtedly performed in accordance with a mutual agreement.

NEW BOOKS AND NEW EDITIONS.—The following have been received for review: Schematic Anatomy, by W. P. Mears, M.B. Leprosy in British Guiana, by J. D. Hillis, F.R.C.S. On Diseases and Injuries of the Eye, by J. R. Wolfe, M.D. Descriptive Catalogue of Specimens Illustrating Surgical Pathology in University College Museum. Scrofula and its Gland Diseases, by F. Treves, F.R.C.S. Only a Twelve-month, or the County Asylum. Elements of Pharmacy, Materia Medica, and Therapeutics, by William Whitla, M.D. Braithwaite's Half-yearly Retrospect of Medicine, Vol. LXXXIV. Transactions of the International Medical Congress, Vols. I. II. III. IV. Statistical Report of the Health of the Navy for 1880. Report upon the Broadmoor Criminal Lunatic Asylum for 1880. Report on the Sanitary Condition of Wandsworth during 1880. Religio Medici, by Sir Thomas Brown, edited by W. A. Greenhill, M.D. Antiseptic Surgery, by W. Watson Cheyne, F.R.C.S. Science and Culture, by Thomas Henry Huxley, F.R.S. "Transactions of the Pathological Society of London." Vol. XXXII.

NOTICES TO CORRESPONDENTS.

ALL CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

DR. BUCHANAN (Glasgow).—We hope to find space for the correspondence "On Protected and Unprotected Small-pox" in our next.

DR. PEIRSON is thanked for his good wishes, and for the information contained in his letter.

DR. A. N. BELL.—Sorry we cannot further add to our Exchange List.

MR. FLETCHER.—An explanation of the circumstance referred to will be found on reference to our "Literary Notes" column, present number.

A SUFFERER.—We do not prescribe in these columns; as you appear to have been fleeced of your all by the quacks, we would advise you to present yourself as an out-patient at the nearest hospital.

VACCINATION.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your answering the following queries at your earliest convenience:—

1st. If a poor woman brings her child from an adjoining district to my dispensary, or to my house for vaccination, is it illegal to vaccinate the said child? and am I, on registering the result of the vaccination and forwarding the usual certificate, to the registrar in whose district the birth occurred, entitled to the usual vaccination fee?

Yours truly, H. D.

[1. It is not illegal to vaccinate any child brought to you for that purpose; but, probably, your question is meant to be—is it illegal to charge the guardians for such vaccination? The dispensary regulations require you to vaccinate all persons who may come to you for that purpose at the dispensary, and it is your duty to return each case in your report (Form H.) which you vaccinated in your capacity as dispensary medical officer, and have not received a fee for. Under the 6th section of the Vaccination Amendment Act of 1879 you are entitled to 2s. for every person successfully vaccinated, and every person re-vaccinated by you within your dispensary district.—ED.]

MIDWIFERY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—What would be the etiquette in the following case: If the wife of a dispensary doctor comes up from the country on a visit to her friends in my district and labour sets in suddenly, and I am called in to attend her by her husband (the case being a serious one), and having paid the usual number of visits, &c., am I entitled to my fee or not? Is it the custom of medical men to take fees for attendance on the wives of their professional brethren?

Yours, &c., E. B.

[It is customary not to take a fee for attendance of any kind on any member of a brother medical man's family. Your professional brother will doubtless do as much for you.—ED.]

MR. MURRAY (Edinburgh) is referred to the notice in our last issue, page 40.

AMBULANCE.—A meeting was held at the suggestion of the Central Executive Committee of the St. John Ambulance Association on Monday at St. John's Gate, Clerkenwell, to consider the desirableness of placing those metropolitan police-stations where the Order of St. John litters are established in telegraphic communication with the various hospitals, and further to consider the best description of wheeled transport available for town use. Major Duncan mentioned that at seventy-five of the metropolitan police-stations there were now St. John wheel ambulance litters. A motion was carried on the proposition of Dr. K. Owen, "That in the opinion of this meeting it is desirable that a system of street ambulances should be organised in London." Two other resolutions were carried—viz: "To offer a prize for the best design of horse ambulance, it being considered that the hand ambulance supplied to the police-stations was already perfect;" and "To place all metropolitan police-stations in electrical communication for ambulance purposes with the hospitals, and with one another."

DR. G.—1. No reply has yet been received. **2.** The review is held over for want of space.

DR. J. O. F.—Proof will be sent in due course. You will receive a private note before insertion.

MEETINGS OF THE SOCIETIES.

- HARVEIAN SOCIETY.**—Thursday, Jan. 19th, at 8 p.m. Election of Officers.—9 p.m. President's Address.—Conversations.
- ROYAL INSTITUTION.**—Friday, Jan. 20th, at 9 p.m., Dr. Wm. Huggins, "On Comets."
- ROYAL INSTITUTION.**—Saturday, Jan. 21st, at 8 p.m., Prof. E. Paner, "On Louis van Beethoven."
- ROYAL INSTITUTION.**—Tuesday, Jan. 24th, at 8 p.m., Prof. John G. McKendrick, "On the Mechanism of the Senses."

Vacancies.

- Carnarvonshire and Anglesey Infirmary.**—House Surgeon. Acquaintance with the Welsh language is required. Salary, £100, with board. Applications to be sent to the Secretary on or before Feb. 11.
- Charing Cross Hospital.**—Assistant Physician. Applications to the Secretary on or before Jan. 28.
- General Hospital, Birmingham.**—Assistant Surgeon. Applications must be sent to the House Governor on or before Jan. 30.

Great Western Railway.—Medical Officer. Salary, £600. Applications to be addressed to the Secretary, and must be delivered at the Paddington Station, London, not later than Jan. 28. (See Advt.)

Mercer's Hospital, Dublin.—Resident Medical Officer and Apothecary. Applications to be sent to Mr. James Shaw, at the Hospital. (See Advt.)

Royal Cornwall Infirmary.—House Surgeon. Salary, £120. Applications to be sent to the Secretary, Royal Cornwall, Infirmary, Truro, before Jan. 25.

Royal Surrey County Hospital.—House Surgeon. Salary, £75, with board. Applications to the Secretary, Town Hall, Guildford, before Jan. 30.

St. Asaph Union.—Medical Officer for the Llanfalfthalarn District. Salary, £81, with the usual extras. Applications to the Clerk, Union Offices, St. Asaph, Flintshire, by Jan. 25.

St. Olave's Union.—Resident Assistant Medical Officer and Dispenser. Salary, £100. Applications must reach the Clerk not later than Jan. 20.

West Herts Infirmary, Hemel Hempstead.—House Surgeon and Dispenser. Salary, £100, with board, &c. Applications to be forwarded to the Secretary on or before Feb. 1.

Wolverhampton and Staffordshire General Hospital.—Honorary Physician. Applications to be sent to the Secretary not later than Jan. 30.

Births.

- BROWN.**—Jan. 12, at 17 Hartington Place, Eastbourne, the wife of Chas. Brown, M.D., of a son, prematurely.
- MAYBERRY.**—Jan. 8, at Riversdale, Kenmare co. Kerry, the wife of Francis George Mayberry, M.B., M.Ch. T.C.D., of a daughter.
- O'BRIEN.**—Jan. 13, at Stoke, Devonport, the wife of Surgeon-Major Hy. O'Brien, M.R., A.M.D., of a daughter.
- SHACKLETON.**—Jan. 9, at Tandraee, the wife of Edmond Shackleton, M.D., of a son.

Marriages.

MARSHALL—PRICE.—Jan. 11, at St. Mary's, Brecon, Joseph Marshall, M.B.T.C.D., second son of the late Joseph Marshall, M.R.C.S.E., of Dromore, co. Tyrone, to Jessie Sarah, eldest daughter of the late Rev. Howel Price, rector of Llanytrithyd.

Deaths.

- BAIRD.**—Jan. 10, after a few days' illness, at 7 Camden Crescent, Dover, Andrew Wood Baird, M.D., M.R.C.P. Edin. and Lond., Physician to Dover Hospital.
- EDGCOMBE.**—Jan. 10, at Upper Norwood, James Edgcombe, M.D. St. And., aged 76.
- HALLOWS.**—Jan. 4, at Canterbury, P. Blackwood Hallows, F.R.C.S., in his 81st year.
- PURDON.**—Jan. 8, at Belfast, Charles D. Purdon, M.D. Dub., aged 63.
- SOUTH.**—Jan. 8, John Flint South, F.R.C.S.E., of Blackheath Park, in his 85th year.
- TAYLOR.**—Jan. 7, at St. George, Guernsey, after a few days' illness, Joseph Marmaduke Taylor, Surgeon-Major, late Royal Horse Guards, eldest surviving son of the late Joseph Henry Taylor, Lieutenant 9th Light Infantry, of Hillbrook House, Castleknock, co. Dublin, and of Graigue, co. Tipperary.
- WILLIAMSON.**—Jan. 6, at Florence, of typhoid fever, Robert Isherwood Williamson, F.R.C.S., M.A., M.B., and Radcliffe Travelling Fellow in the University of Oxford, aged 20.

CRUELTY TO ANIMALS.

The Dublin Society for Prevention of above, APPEAL for Help to extend their labours.

Cases detected since 1st January, 1881 (as many as during the week of last year):—

Horses	315
Donkeys	30
Mules
Cattle	11
Fowl	23
Pigs	5
Goat	1
Dog	1

Total .. 389

The Society's Officers have no pecuniary interest whatever in Prosecutions, Convictions, or Fines.

WATER TROUBLES.

The Committee wish to Erect Two Fountains, much needed in the city, and hope the humane public will lend their assistance with funds.

Any notice of Cruelty cases, or Donations will be thankfully received by GEORGE RYALL, Secretary, Office, 36 Westmoreland Street, T. F. BRADY, Esq., Hon. Secretary, 11 Percy Place; or WM. PERKIN, Esq., Treasurer, 60 Lower Sackville Street.

MIDWIFE in a DISPENSARY DISTRICT.—A FULLY-QUALIFIED NURSE, Experienced and Active seeks an Appointment as above. Can be highly recommended by the Dublin Editor of the *Medical Press*, to whom application may be made.

DOUBLE QUALIFICATION, EDINBURGH.—STUDENTS are prepared by a "successful" Candidate, F.R.C.S.E., Messrs. E. & S. Livingstone, Edinburgh, for the Edinburgh.

The Medical Press & Circular.

TWENTY-ONE YEARS OF SCIENTIFIC PROGRESS IN THE USE AND DISUSE OF ALCOHOL.

By B. W. RICHARDSON, M.D., F.R.C.P., F.R.S.,
President of the Sanitary Institute of Great Britain.

(1.) I REMEMBER that twenty-one years ago it was a very common notion—one of the most common of all notions—that wine, beer, and spirits were things quite distinct from water. The common impression was that when these things were taken they were distinctive agents of themselves, that there was no water connected with them according to ordinary acceptation, and even through our better classes this view was constantly expressed. A gentleman sitting at table would tell you that it was the best champagne he provided, no watery stuff, and that he had given say £7 a dozen for it. You were under the delusion if you took the man's word that this was no watery beverage, but something different. You found the poor man at the inn, smacking his lips and saying, "This is no water, it is good malt and hops." So a person taking a glass of spirit which burnt his lips and throat thought it all the better the hotter it was, "because," he would say, "it is farthest removed from water." There is no doubt a great advance in the public knowledge on this one topic. We, as men of science, have so impregnated the public mind with the facts that there are very few now who do not know that the fluids sold as beer, and wine, and spirit are always largely water. The bottle of champagne, which costs so much per dozen, when it comes up for investigation, turns out to be a fluid of which, if you take one hundred from eighty to ninety, are water. If you turn to the beer which the man is drinking at the inn, you find the same relative story. So with regard to spirit. In sherry there will be three parts of water to one of spirit; in brandy, that strongest spirit, fifty of water to fifty of spirit. Now, I think, through the length and breadth of the land, these facts are making an impression, and those who are not engaged in the question of scientific research can use them as forcibly as we can. They can explain that people who think they are paying large sums of money for something exceedingly choice, are after all unwittingly, and in a very unfortunate way, water-buyers and water-drinkers.

(2.) When the idea of spirit was brought forward, and we talked of the strength of beers, wines, and spirits, it was thought that one particular alcohol or spirit was the only thing of its kind. Men of science knew better, but the general impression was, and is to some extent still, that the substance which we call spirit is a thing alone of itself, that it stands as though there was nothing else like it. I hope we have pretty fairly imbued the nation with the fact that this spirit of wine is only one of a great family; that there are a number of alcohols, some derived from wood, some from wheat, some from potato spirit, and so on—all bodies of the same chemical family, and not in any way distinct, except by the simple accidents of taste and weight, and a few other physical varieties, from that alcohol which we drink.

(3.) I think we have fairly brought out what in regard to the effect of the particular alcohol we take that it can in no way be considered a food. We have shown that foods are substances which either make up the great mass of the body, like water; or which build up the tissues, like albumen, egg, cheese, meats; or which burn in the body, like fat, and oil, and starch, and sugar, producing animal warmth and keeping up the vital fire; or which go to make up the bony structure. We have shown that alcohol does not belong to water food; that there is nothing in it which it can represent in regard to meat substances; or the same with the structures which make up the skeleton of the body. Then, when we ask whether this agent can be classed with the foods which keep up the animal warmth, we find that its imbibition reduces the animal temperature and prevents the formation of those products which come from the burning of food within the body. Therefore, so far as alcohol is concerned, we can affirm that positively it is no food at all, that it produces phenomenal effects upon the body, is no more a food than chloroform and ether are foods.

(4.) Again we have traced out that alcohol acts just as do other phenomenal agents. Men of science have come by a common consent to this position, that there must be a certain point when the quantity taken must not be exceeded. There is not a single physician living who is a thoughtful man, who would not tell you candidly and honestly in this day that there must be a very strict border line drawn as to where the luxury must stop. Twenty years ago men did not think of a limited number at all. "Oh?" says the man who wishes to please all parties—"you may take a little

but it must not exceed the physiological quantity"—not more than you can by your good health dispose of without injury to yourself. "You may take 1½ oz. of alcohol if you like in the twenty-four hours." That means a very small quantity indeed. It would be represented by two to three glasses of ale. "You may take that in the twenty-four hours, but you must not exceed that quantity. If you do, then you run the certain risk of slipping into disease." Thus we have brought the matter of quantity down to a very fine point indeed—and some even reduce the quantity still lower.

(5.) Twenty-one years ago it was a common belief that men did more work when they took a little drink—not a little, I think I am wrong there, but when they began with a little and went on, great feats were said to be performed by men when they were taking the drink, as if the taking of the drink was a necessity for the feat. Science has shown that there is no strength got by alcohol, that it is perfectly impossible that that which does not build up the tissues of the body, does not supply water, warmth, and vitality to the body, can give strength to the body; while numbers began to try to abstain independently of science, and so two favouring currents set in. Now what are the recognised facts? That all men who are going into training, for rowing, long walks, and the like—whatever they are going to do with regard to training for these pursuits discover the advantage they get if they altogether abstain from the use of this degrading and debasing physical agent—alcohol.

(6.) Another advance has been made in regard to *mental work*. I remember the time, when if it was conceived necessary to write at night, a man must needs prime himself with wine or spirits. Here, again, our scientific research came into play, and we have been able to show positively that nothing is so injurious to mental work and capacity as for anyone to lace himself up with strong drink under the idea that he is assisting himself. All our medical authorities at this day proclaim that as the general fact; and they proclaim it from reasons which are seen fearfully standing out day by day in the most glaring colours, and on the most unmistakable lines. The very best of men (such is the evidence) have fallen from this idea, that being engaged in mental or artistic work, they would gain assistance from an agent which, of all others, is to them most enticing and most perilous. It is men of this class who most readily succumb. This impression of evil from alcohol has had its influence all through society, but whether there is a great reaction in favour of the simple rules of nature or not, this is quite certain, that the evidence that should lead to such reaction is now fairly and fully before the world, and has been put before it by the labours of those who have worked on the scientific basis during the past twenty-one years.

(7.) Twenty-one years ago, except among the total abstiners themselves, it was believed that to meet the vicissitudes of cold and of heat, it was necessary that a certain amount of alcohol should be taken; and so our ships went out to the Arctic regions charged with spirits to "assist" the men, and our soldiers were sent out to India charged with spirit rations to give strength to them. Look at the extreme absurdity of this practice. If the men that went due North had this alcohol to warm them, the men that went to tropical climes could not want it for warmth. Did they want it to cool them? What is the evidence? We have proved that under cold there is nothing so bad as this spirit, and that it is, as it were, death added to sleep. We have proved that when the temperature of the body is raised by extreme warmth there is nothing so bad as the tension produced in the blood by this light vapour of alcohol. We have shown through science what is the effect of alcohol in heat and cold, and have shown that in both cases it must, from the nature of its action, be ruinous to health and life. That has had a good effect. We know now that those men who have been total abstiners have lived best, worked hardest, suffered least, and came home soundest in heat and in cold. We know that in the tropics those men who have taken least have fought the hardest battles and made the best marches; and those who have taken none at all have been better off still. In tropical weather we have found that the mortal disease which kills so many and which is called sunstroke—that the people thus stricken are not all persons in perfect health, but those who have prepared themselves for the direct effect of the sun upon them by the introduction into their systems of alcoholic drink.

(8.) Twenty-one years ago it was supposed that persons

could live for a certain length of time upon alcohol, and one of the hardest nuts we have had to crack has been to meet this statement. It was very common to give to weak and feeble persons wine and strong drink, and they lived upon that, as it seemed, so well that nobody could be convinced that this was not good living in certain cases of weakness and exhaustion and want of other fluid. As we have thought over the matter the facts have come out, that what is most wanted by these starving people, that which keeps them alive is not the alcohol, but the water that is commingled with it. The person who is said to take a bit of rusk, and with that so much gin-and-water or champagne, has not been living by virtue of alcohol or spirit, but by virtue of the water that has been taken with that limited fare; and we have come to a positive conclusion and knowledge that a man may go on for days and weeks, and may live as it were upon himself, if you will simply supply him with a sufficient quantity of water.

(9.) I recollect twenty-one years ago that alcohol was considered the grand *panacea in the treatment of diseases*. For my part, though I had not then become a total abstainer, I had always stood aloof from the method of treating all descriptions of disease, and particularly diseases of an exhaustive kind, with large quantities of alcohol. In my student life I observed in cases of fever that the free administration of alcohol always produced a great deal of excitement first, and then depression, and then sleep, and a delirium which did not seem to be very different from the delirium of drunkenness; and yet under the influence of masters who said this was necessary a student was obliged to accept that that was the right treatment. Later in life when I began to practise for myself and found a very distinguished physician praising this treatment in all directions, and a number of disciples following him, I was obliged to hold aloof and be somewhat unpopular because I would moderate the quantity of spirit that was being given. Then gradually the truth began to dawn upon me and others that the thing was all wrong; and through the great efforts made by a very few men in the first instance what is the result? That the whole of this heroic line of treatment of disease, not by ounces of wine, but of pints per day, has been altogether given up. The idea of the wine or spirit treatment of fever has passed nearly away. To Dr. Gairdner, of Glasgow, we are greatly indebted. With a boldness which few men under the circumstances would have evinced, he eliminated these stimulants from his fever wards one by one. He found persons come in there sick with the disease and die at the rate of 36 per cent. In from two to three years, with true conservatism, by reducing the quantity of alcohol until he brought it to a minimum or to nothing at all, he got results of deaths at the rate of 8 or 9 per cent. We were all struck by this, and you will find wherever you go that this treatment of disease by large quantities of drink has passed into oblivion, never, I hope, to rise again; has passed away with results at which everyone wonders, with results in recoveries which never could have been hoped for if, by a slow and gradual process, from that which was—yes, I will say it boldly—vicious and dangerous, and even fatal, a different system had not been carried out.

(10.) Twenty-one years ago we attributed but little to alcohol as a cause of disease. We said there was a disease called gin-drinker's liver, and that this was attended afterwards with dropsy, and led to a certain fixed mortality. We know well also of *delirium tremens*, and of *mania potu*, as the French call it, or "dipomania," as we call it, and not much more. You will, however, find now that the word *alcoholic* has become a common adjective in language referring to disease. Men speak of alcoholic phthisis or consumption. I was first to observe that there was a particular form of consumption, very fatal in its character, which was peculiar to persons who indulged largely in alcohol, which was specifically *alcoholic consumption*. That has been accepted, and later on other forms of disease—liver disease, heart disease, paralysis, apoplexy, various forms of dyspepsia, premature old age, and death are often accepted as alcoholic. You will hear that a man has got alcoholic paralysis, has died from apoplexy the result of alcohol, is prematurely old from alcohol: that is the evidence you get now; but you did not get it twenty-one years ago. The facts had always been as they are, all history had told the facts; but they had not been analysed and traced to their true source. We had not known that it was from the influence of this one particular agent that all this vast mass of disease was springing. A professional brother, going further than I even would have gone, has said that in walking his hospital for

twenty-five years he has been led to the conclusion that sixty to seventy of the cases of disease which came there were cases of disease brought about either directly or indirectly by this one agent alcohol.

(11.) We have known always that when a man or woman sits down at table and begins to take wine too freely, there is a stage of excitement, another stage of more excitement, another stage of wasted excitement and coldness and pallor, or darkness of the face; and a final stage, when the body lies helpless, or, as we should call it, dead drunk. That was known as regards the first effects of alcohol. What do we now know? We know that the slow, insidious effect of alcohol upon persons taking it day by day and year by year, at last gives us great populations who, not being intoxicated in this special or acute form, are still its victims in the same way. We know there are populations who go about and just take the "physiological quantity" which brings them up to the first stage; populations who, beginning rather early in the day, go from bar to bar, and place to place, perpetually in the second stage; populations who go on day by day and never go to bed thoroughly sober, or out of the third stage. And, when we go into our asylums and hospitals we find the victims of alcoholic paralysis, who, unable to help themselves, are practically speechless and practically dead drunk from the permanent use of alcohol have advanced, in this slow, insidious manner, into the fourth stage, in which they are ripe and ready to drop into the grave.

(12.) Twenty-one years ago, the facts about disease and short life from drink not being well recognised, our insurance companies were blind to them; but now so keen are they on this question of the effect of drink upon the persons who come to be insured that on the lives of those who sell strong drink there is put actually an extra tariff, and the great question asked by the insurance company is the question of sobriety.

(13.) We have figures in regard to the mortality from this agent strong drink which are startling, and which twenty years ago we should never have conceived as possible. Lately we have got much more refined examination of facts than formerly, although there has been a difference of opinion as to the real mortality from the use of strong drink. Dr. Farr, who thought that the mortality was very much overrated, has since said that forty to fifty thousand persons die per year from what he calls 'tippling.' Dr. Farr, before he resigned his post, was as good as to allow me to examine some returns of his, and this came out as a startling fact that there were variations in mortality from 71 to 138, 100 being the standard; this is to say, if the mean mortality of seventy occupations in three years examined was 100, then in the most favourable occupations the deaths were as seventy, and those in the least favourable were down to considerably over 100.

(14.) As regards insanity. Exactly in the same way as the body ceases to exert its proper powers under this agent so the mind begins to fail. There is great difference of opinion as to the amount of mental disease produced by alcohol. Twenty years ago the subject was not much under discussion, now it is, and the Commissioners are now reporting upon it. There is a difference of opinion, but it is generally admitted that there is a very large amount of insanity produced by drink, directly or indirectly. Dr. Edgar Shepherd declares that 40 per cent. of the persons who come into the great Asylum at Colney Hatch are brought there by the direct or indirect effects of drink. The Royal Commissioners say that the direct effects are represented by 14 per cent. It is difficult to get at the direct, and separate them from the indirect effects. But apart from that—see what an important point has been brought forth. I hold in my hand the record of 232 cases published by Dr. Mason, of Fort Hamilton. Dr. Mason shows, from the persons who have been under his own care, that it is not the poor and the badly educated, but that all classes are affected through this agent, and are represented in his asylum. He says, "We have at present amongst our patients clergymen, lawyers, physicians, and representatives from all classes of society, who once held remunerative and responsible positions, but who now, voluntarily in many instances, seek the shelter and restorative aid which our asylums afford." He goes on to say how this inebriety is brought on and produced by the drink, and he would put as mental alienation from drink the estimates higher than those of Dr. Edgar Shepherd. You see what a lesson this is to us, that there should be not only the physical, but the mental death so distinctly brought out by the use of alcohol.

(15.) Another point, and it is a sad and impressive one. Twenty-one years ago we had no kind of knowledge of an exact nature with regard to *heredity and drink*. Dr. Connolly, the late Sir John Forbes, and Dr. Carpenter had hinted and pointed out the relationship of drink to certain forms of hereditary disease; but we had no conception how marked is the influence of alcohol to produce disease by heredity, that is to say, not only in the person directly affected, but in the offspring of that person. We know now as certainly as possible that the thoroughly inebriate man or woman having children impress those children distinctly with the diseases which spring from the use of this particular fluid, and here we have again Dr. Mason coming forward and telling us:—"The inebriety of parents should be regarded as one predisposing cause of insanity in the children. The principal cause is the inebriety in the parents—92 of 116 cases in our asylums have such a percentage."

(16.) Again, we have had brought out before us in a manner never before the *relationship of alcohol to crime*. Our judges now are alive to this subject. Some have said that 90 per cent. of the criminal cases come from this cause, and this very day the papers contain a charge by Mr. Justice Kay, in which he says judicially, "I know by my experience that 50 per cent. of the crime of the kingdom springs from this cause."

(17.) We have declared that alcohol prepared and taken on a large scale is a source of starvation—that to take large quantities of it is to starve. We have known that all through our history. Our painters have shown that. Our Hogarths and Cruikshanks have sketched that. All who have depicted drunkenness have connected it with want and penury. We get now beyond that. We see the nations that are going to suffer severely, are nations that destroy the produce which is given to them for the supply of their natural wants by appropriating it to unnatural productions. For instance, in Ireland, one of my friends has brought me a book on the culture of land in Ireland, and has shown that 75 per cent. of the cereal produce of that country goes for the production of one grain—barley, which goes in its turn for the production of one destructive drink—whisky. Let us take that to our minds; and that is only one illustration of which many more could be given; but we have here this broad fact before us that directly we begin to take food for a false purpose we take from ourselves that which nature wished us to have, and starvation, misery, and penury are the natural results.

(18.) We have gained a piece of information we had not twenty-one years ago. Twenty-one years ago it was common to say: "What the total abstinents urge is right enough, but we are accustomed to the use of strong drinks, and are unable to leave them off; it is dangerous to leave them off. You must not break through a habit. You must be moderate." On that point we have grand experiments going on in our model prisons. We know that those unfortunates who are locked up, are locked up directly from this agent. When my mind became turned towards the action of alcohol upon the body I said: "Here is a crucial test about the leaving off." I inquired of the prisons, "Do you let these people down drop by drop, and gradually reduce strong drink?" "No," I found was the response. As the prison-door closes the tap closes so far as they are concerned. Then I asked "Do they suffer in any way?" The answer was "Never!" And wherever I have made that inquiry into discipline and life I have never once found an instance where it could be shown that the sudden leaving off of this drink by these people was a cause of any disease or any kind of defect whatsoever.

In America and Canada we have had the same experience. Dr. Bucke has recently published some experiments he has conducted. In 600 cases he has removed suddenly strong drink, and he says his asylum was never in better condition, and that he has never had the least occasion to suppose that the slightest injury was inflicted. For the moral side of our question this is a fact of supreme moment for you to bear in mind.

(19.) We get to see that through history there is a great deal to be learned in regard to what has been the cause of the failures of nations. Historians are now beginning to look up and say there were great wars at various times. How did they spring up? Who were the men that led them? They look at those great strifes that led to the American Revolution. Who were the statesmen? Why, they were statesmen who were always in wine. Look at the great riots and troubles that have arisen. What was their origin? Wine and strong drink. Even Alexander the Great is spoken of as

"Alexander the Drunkard," and it is known that he died intoxicated. Historians will soon be able to pick from the history of the past that which was sober and that which was drunken in the history of mankind and of nations.

(20.) We have scored a point in legislation. Twenty-one years ago no statesman would have dared to think of legislation as touching the English Juggernaut. On the contrary, he would let our people roll under its wheels, and be killed wholesale, and think nothing about it; but now it is the ambition of statesmen to lead the van of temperance, and by-and-by Sir Wilfred Lawson would have more compeers perchance than he liked were it not that his heart is as sound as his head.

(21.) Lastly, we have given up the notion pretty generally—those who are men of science and of thought have—of alcohol as a necessity. That general expression of alcohol as a necessity has passed from our minds by the accumulated evidence derived from so many sources. We speak now of alcohol as a plague, we say it produces fever and kills; we speak of this as a pestilence, we say that it infects, and spreads, and devastates.

Twenty-one years ago we used to hear in our churches the minister pray, "From plague, pestilence, and famine, from battle and murder, and from sudden death," and we used to hear the congregation give the response, "Good Lord, deliver us." Now by the knowledge we have we declare:—Yes; plague, pestilence, and famine, battle, murder, and sudden death, are all more or less linked up with this one agent, and we declare also that if we could say, and not only say but ensure ourselves, that we were delivered from this one agent, then the rest of our deliverance is indeed at hand.

THE LAWS WHICH GOVERN THE EXCITING AGENTS OF EPIDEMIC, ENDEMIC, AND INFECTIOUS DISEASES.—No II.

By JOHN GROVE, M.D.

(Continued from page 46.)

THE diffusion or dispersion of everything that lives no one can imagine to be conducted without reference to order, system, or law.

In the investigation of this law, by which the agents of disease become disseminated, or, as it may be called, the law of dispersion, we have but to refer to our own individual experience to discover its principles. We know that the agent of whooping-cough floats in the air, and that the poison of fever is wafted to a distance by the breezes; we know that the virus of small-pox, barely sufficient to moisten an ivory point, may be dried, wrapped in a piece of paper, and enclosed in a chest, it may be transported to any part almost of the habitable globe, harmless as the ivory on which it rests, or the paper which enfolds it; wherever may be its destination, it has but there to be placed in circumstances and under conditions for its dispersion on new lands, or in foreign climes, and its work of propagation and extension proceeds. We carry about with us the invisible poison-germs of scarlet fever, measles, and erysipelas, and are their unconscious disseminators. Waters flowing through paludous districts may, and do carry the poisons of cholera and dysentery, so that those who drink of them become affected with these diseases. All this is well known. But what do we gather from these facts?—that, by the air, by the water, and by the hand of man, the dispersion and diffusion of the germs of disease have been brought about, and by the same means also has the earth become clothed with vegetation, and the water and the land peopled with their multitudes of animal existences.

The law of static existence which is exemplified in the seed of plants and in the ova of animals, is remarkably illustrative of the doctrine here set forth.

The equilibrium of force which obtains in the seed or the ovum, is that relation of the component atoms of organic matter by which they are sustained in a condition requiring only a determinate train of circumstances to develop a series of phenomena. This series of phe-

nomena, viz., growth, maturity, and decline, wherever they are found, indicates as a sequel, the tendency and design of a multiple repetition of similar series. The seed is sown, and the ovum impregnated, the equilibrium of force is disturbed, the period of static existence has terminated, the formative power is at work, the death of the old and the generation of the new is the sum of the result. It is in this generation of the new, that the condition of static existence again appears in the newly created germ. All this is manifest in the inoculation of small-pox, or in the communication of any disease by contact. But beyond this, the period of static existence, whether of the seeds of plants, the ova of animals, or the germs of disease, has certain limits, and is regulated by a law. Further, in a given time, all alike yield to the dominion of the physical forces, chemical affinity, heat, light, and electricity. It is but in our day that well concerted experiments are being made to determine the duration of the latent life of seeds, and, fortunately for the botanist, his experiments can be conducted without risk or injury to any person. With a fair amount of caution and precision he may calculate upon arriving at a considerable amount of valuable information in a course of years; but the pathologist is less fortunately circumstanced; the experiment of sowing the seeds of disease among the human species would be unjustifiable (except in the case of cow-pox) and it would be highly interesting to know how long, under favouring circumstances, this virus might retain its power; this, with some other matter of disease laid by for experiment, after the manner of the botanist's seeds would not be altogether without its fruits. Without reference, however, to experiment, we are all satisfied that the matters of disease have a power of resistance to change or decomposition, and that the period during which they can retain this power, though not at all defined, is nevertheless known to extend over a space of some years in a few instances, perhaps only over a few months or weeks in others.

It is sufficient here to point out the fact that the elementary matters of disease possess a static power of resistance to change, and that, while that power remains, they are capable, like the seeds of plants, under favouring circumstances, of taking on an active state of existence, viz., of growth and reproduction.

The three following laws I will take in conjunction for the purpose of condensation. Every thing that lives has a limited period of active existence. Reproduction is intermittent. And there is a specific period of development.

There is a law by which the active existence of all that lives is governed and limited; man in his pride, the beast in his strength, the plant in its beauty, the insect in its agility, all at length succumb, at varying periods, to the dominion of this law. Pride, strength, beauty, and agility are the resultants of the active formative power of the original germ, which in the first instance has elaborated a highly organised nervous mass, the brain of man; in the second, the muscle, bone, and sinew of the beast; in the third, the gorgeous petal, and the delicately varying green, reflecting chlorophylle of the plant; in the fourth, the airy form, the pliant limbs, and gauze-like wing of the insect. Each has its limited sphere of action, each reproduces its kind, at intermittent periods, and each progresses to development by regularly defined stages. And are not the germs of disease limited in the sphere and time of their activity? Do they not, at intermittent periods, reproduce their kind, and progress to their development by definite stages?

I have now but sketched the main features of those laws, which, for distinction, I would call the objective laws of living things, for they refer to properties or tendencies inherent in the things themselves.

The following laws I have designated subjective, because they affect those properties or tendencies, and originate in the influence of external agents and circumstances.

There are seasons of extraordinary productiveness, both in animals and plants; at present we are unacquainted with the cause of peculiarity, but so distinct and certain is the fact, that we are compelled to acknowledge it as a law appertaining to the animal and vegetable creation. We are the more cogently led to this conclusion by the coincidence, that after great mortality by epidemics, there has always been an unmistakable and unusual increase in the proportion of births over and above the ordinary range; the peculiarity is the greater because those who fall victims to pestilential diseases are most chiefly in the limits of reproductive age.

Here we seem to recognise the workings of a watchful spirit. There are seasons of abundant and scanty harvest, to us, observing uncertain intervals, but obedient to some unseen mysterious operations of Nature's laws.

There are seasons when the germs of disease are unusually rife.

In the first six months of the year 1838, the poison of our indigenous typhus was remarkably active, and in this metropolis it carried off 2,461 persons; in the corresponding months of the following year, 1839, but 1,045 succumbed to its influence, being considerably less than one half the number of the previous year.

The influence of climate upon living beings, whether animals or plants, has long been noticed; I do not purpose entering upon the particulars of climatic influences. The atmospheric variations as to warmth, moisture, winds, and barometric and electric disturbances are the chief elements concerned in the modification of climate; (a) to these the functions of organised bodies have ever shown a manifest relation; under some combination of atmospheric phenomena observing a regularity and evenness of action, and under others exhibiting disturbance of equilibrium; moreover, climate may in some instances so far interfere with the organisation, as sooner or later to extinguish the vital functions; sometimes its effects are only seen in the dwindling and degeneration of the species, at any rate, the properties of plants are much affected by the modifications of climate. To pursue this subject would lead me far beyond prescribed limits; suffice it to say, that similar effects are known to occur, and be operative on the agents of disease. It has been observed that the vaccine virus (b) loses much of its power in Bengal upon the approach of the rainy season; recovering it as the cold weather returns. The agents of disease are even perhaps more susceptible of climatic change, than matters which come more especially under the cognisance of our senses. A change of wind, an increase of wind, a variation in temperature, have all been observed to check or suspend the progress of development of the agents of epidemic and infectious diseases.

The influence of latitude and geographical position are still more remarkable than that of climate. The following is an illustration of this curious fact. It is taken from Dr. Drake's work on "The Diseases of North America."

"Yellow fever, which has repeatedly prevailed in almost every town up the Mississippi to Vicksburg, N.L. 32° 24", has never but once reached Memphis in 35°, and has not prevailed at any intervening town. Thus its limits, on the whole, have been those of the live oak, cypress, and long moss, and it will not, any more than they, be found among apple orchards, wheat fields, and groves of blue ash, sugar-maple, and the aborescent buckeye."

It certainly is not to temperature alone that the vegetation of the Tropics owes either its splendour or its other sensible qualities. Many facts go to prove this view. I therefore consider that a distinction should be drawn between climate and latitude, or geographical position.

Dr. Lindley quotes the following:—

"In respect of the predominating kinds of grain, the earth may be divided into five grand divisions or kingdoms—the kingdom of rice, of maize, of wheat, of rye, and, lastly, of barley and oats." And we may say that, as there are kingdoms which produce grain for the food and sustenance of man, so are there kingdoms which produce the seeds of disease for his discomfiture and destruction. There are the kingdoms of yellow fever, of plague, of dysentery, and of typhus.

We now come to the effects of artificial heat and cold on the seeds of plants, the ova of animals, and the germs of disease. The ova of animals do not afford us any information beyond those facts connected with the oviparous tribes. It appears that the temperature at which albumen coagulates—viz., 160° Fahr.—is sufficient to destroy the vitality of eggs. They do not, however, furnish such ready means of experiment as the seeds of plants. It has been found that the starch globules of seeds are not liable to burst under a temperature of 167° Fahr., and that if seeds are immersed in water at this degree of heat for a quarter of an hour, their vitality is destroyed. They, however, bear lower temperatures for a short space of time, and at 125° Fahr. most of them retain their vitality. In dry air many seeds will bear a temperature of 167° Fahr. Of the effect of cold, Dr. Lindley says, "No seed can germinate at a temperature so low as that of freezing, and each seems to have some one temperature more proper for it than any other at the first dawn of its life."

The conditions necessary for the germination of seeds are exactly such as most favour, generally speaking, the propagation and development of the germs of disease—a warm, humid, and dark atmosphere is the most favourable to them. The cold of the winter of 1664 was, according to Mead, sufficient to arrest the propagation of the seeds of the plague.

Dr. Henry showed that the germs of scarlatina were destroyed by a temperature of 200° Fahr., and that most of the poisons of disease were rendered inert by a temperature of 212° Fahr. He further states that the plague, which requires a temperature of 60° Fahr., is perfectly "disarmed" by a temperature of 90° Fahr. The poison of cow-pox is destroyed by a temperature not exceeding 100° Fahr., and he believed that the highest atmospheric temperatures might destroy several of the morbid poisons. Light and electricity, though they have great influence on living things, have not been studied in their effects on the morbid poisons. We know, however, that attacks of epidemic and infectious diseases are considerably more frequent between sunset and sunrise than at any other time.

There is a law by which all living things have a tendency to the selection of locality: it is seen to be in operation very extensively among the animal kingdom, but more especially among the varieties of the vegetable kingdom. To cite instances would only be to reiterate facts universally known. Mead states that, after the suspension of the plague by the winter's cold, it broke out again in the very same house where it commenced. Mr. Grainger, in his report on the cholera, gives the following singular confirmation of the selection of locality by the germs of disease:—"It is a striking fact that, in the midst of all these changes and deviations, the cholera has steadily held its course through one path, so bound is it to definite localities, that, with some exceptions, it has, so far as Europe is concerned, in each epidemic—1831 and 1832, in 1837, and again in 1848—visited and avoided precisely the same countries and the same cities. It has reappeared in the interior of towns, on each occasion, in its old haunts; it has come back, after an interval of years, into the same districts and streets—nay, it has, in various instances, even revisited identical houses, and, it is affirmed, the same rooms." The report of the General Board of Health on the cholera has a further confirmation of this fact:—"The first case that occurred in the town of Leith, in 1848, took place in the

(a) See Humboldt's "Cosmos," Vol. I. Translated by J. P. T. P. 346.

(b) See *Medical and Chirurgical Review*.—Vaccine lymph producing small-pox during an epidemic of small-pox.

same house, and within a few feet of the very spot from whence the epidemic of 1832 commenced its course. On its reappearance in the town of Pollokshaws it snatched its first victim from the same room and the very bed in which it broke out in 1832. Its first appearance in Bermondsey was close to the same ditch in which the earliest fatal cases occurred in 1832. At Oxford, in 1849, as in 1832, the first case occurred in the county gaol. This return to its former haunts has been observed in several other places, and the experience abroad has been similar. At Groningen, in Holland, the disease in 1832 attacked, in the better part of the city, only two houses, and the epidemic broke out in these two identical houses in the visitation of 1848."

I have endeavoured, though I fear imperfectly, to place the subject in that point of view from which, (demonstration being impossible at present) as Dr. Nicholl says, "to deal with probabilities, and judge of vast problems, we must weigh and balance, instead of demonstrate;" and further, "there is little hazard in at any time inferring the predominant or governing influence of some one principle, if, across all modifications, its effects stands out clear and undisguised." And here I would maintain, that to some form of life (most probably vegetable) the principle of epidemic and infectious diseases is to be referred, that the predominant or governing influence is due to reproduction, and that it is during the exercise of the reproductive faculty of the poison-germs, that the phenomena of acute disease are manifested.

In the laws of nature there is always a fact or principle which prominently stands out as an index to direct those who are desirous of interpreting them. The fact, that bodies fall to the earth led to the discovery of the laws of gravitation, and these, as a principle, have led their investigators onwards to the explanation of some of the most wonderful phenomena of the universe. The fact that bodies yield after combustion a greater sum of weight than before the process, led to the discovery of oxygen; and oxidation, as a principle, in the science of chemistry, has, at the hands of Liebig and others, solved many of the most intricate mysteries of life and organisation. I might proceed to weariness with illustrations. I am aware that the extensive reception of an error in science is a serious obstacle to progression, and that the too ready acquiescence in analogies is a dangerous proceeding; on the other hand, a neglect of analogies would much cripple experimental research. It was by analogy that the metallic bases of the alkalis became demonstrated. It was by analogy that the diamond was found to consist of pure carbon. It was reasoning by analogy that led Jenner to the demonstration of the protective power of vaccination. The dictum of Harvey—*omne vivum ex ovo*, had its origin in analogy, and having now stood for more than two centuries, it remains as unshaken as his greater discovery—the circulation of the blood.

It has been said, that supposing the doctrine here advocated be true, so much would still remain to be elucidated, it is scarcely to be hoped that this mode of accounting for disease should be transferred from the rank of a mere hypothesis. I cannot believe there are many who sympathise with these sentiments. Every invention, every discovery almost, has first assumed the form of an hypothesis in the mind of the discoverer or inventor, and had it not been for hypotheses, electric telegraphs, and locomotive engines, hydraulic presses, tubular bridges, and electric lights had never been known.

Is it nothing, in assuming this hypothesis, that we have a ready explanation of many of the mysteries of epidemic and infectious diseases? Is it better to remain in ignorance of the revolution of the earth, and to believe that it stands still while all above is moving round us? Is it better to believe that noxious vapours, miasmata, and mephitic gases mean nothing, and that all the myriads of created beings invisible to the naked eye have no significance? Neither vapours, gases, metals nor metalloids, alkalis nor alkaloids, salts nor secretions, are capable of reproducing their kind; they are therefore inadequate to

the explanation of the first and most important feature of infectious disease, viz., the multiplication of the species.

Neither can the physical forces alone account for infection; it is true that a small spark may create a great flame, but the force of heat, like all forces, is derived, not generated; in the case of combustion, heat is derived from chemical change. There is doubtless much due to the influence of the physical forces in the propagation of epidemic disease. The east to west direction, with other peculiarities, indicates the probability that magnetism or electricity may be the exciting cause of the development of the germs of disease. In the track of certain currents under other necessary favouring circumstances, the poison may be operative, and out of those lines there may be no vivifying influence. The sudden cessation of epidemics in all places, which occurs with such singular uniformity, shows that as the maximum of intensity is gradually attained, so is the decline rapid. Is it not so also with vegetation? The flowers and fruits of the earth, are they not slowly evolved, and step by step matured? And when they have reached their maximum of development, do they not suddenly, in comparison with their evolution, drop their petals and shed their seeds?

Guildford, December, 1881.

Clinical Records.

EAST LONDON CHILDREN'S HOSPITAL.

A Case of Hæmaturia—Subsequent Passage of Renal Calculi.

Under the care of Dr. EUSTACE SMITH.

(Reported by Mr. SIDNEY DAVIES, B.A., M.R.C.S.,
Clinical Assistant.)

WILLIAM THOMAS COX, æt. 6, was admitted into the Children's Hospital on October 31, 1881, suffering from hæmaturia.

There was no history of gout or gravel on either the mother's or father's side. On the mother's side there was a history of morbus cordis. The patient and a brother had enlarged cervical glands.

The patient's previous history was as follows: He had been brought up at the breast, and weaned at sixteen months. He was healthy at birth, had measles when eighteen months old, and scarlet fever in October, 1880. He was ill with the last-mentioned exanthem for thirteen weeks, and had dropsy and smoky red urine. The abdomen was swollen and the face puffy for eight weeks. His brother and sisters had scarlet fever and dropsy at the same time.

He recovered from this illness at the end of February last, and remained well till the end of April, when the smoky red condition of the urine returned, but was unaccompanied by dropsy. The urine passed was said to be dark brown or black, and sometimes scarlet, this condition not being continuous, but occurring chiefly in the urine passed at night and early morning, the mid-day urine being generally paler. The patient had no severe pain at this time, but occasionally complained of slight pain in the left groin and hollow of the left thigh. A change of air being recommended he was taken to Dover, where, after three weeks, his urine returned to its natural colour. He returned home in August, and remained well till October. One day at the commencement of October he got wet, and the hæmaturia returned, but it caused him no pain or inconvenience, his general health being quite good.

The urine brought for examination was tested after standing some hours. It was porter-coloured, rather thick, and faintly acid.

After admission no urine was passed till the following morning, when twelve ounces were obtained. This was smoky, depositing a thick granular sediment, and contained about one-fifth albumen. Under the microscope it was found loaded with granular matter, but containing no casts. There were some few uric acid crystals and amorphous urates. The addition of nitric acid showed no excess of urea.

Nov. 2nd.—Fifteen ounces of smoky red urine passed.

3rd.—Twenty-two ounces of clear urine. Sp. gr. 1016. No albumen.

4th.—Dr. Eustace Smith examined the abdomen and found nothing abnormal. Skin not rough. Ordered—

Liq. ammon. acet., ℥j ;
Pot. acet., gr. xx ;
Tr. scillæ, ℥x ;
Tr. digitalis, ℥x ;
Aq. ad., ℥j.

Ter die sum.

Mist. salis. aperientis, ℥j.

Alt. nane.

6th.—Twenty-five ounces of urine passed at different parts of the day clear at one time, smoky at another.

From this date until the 15th the occurrence of hæmaturia varied from day to day, and at different times on the same day. From the 15th it became much less frequent, but still occurred at intervals. until he went out on the 26th of November.

On November 11th Dr. Eustace Smith ordered the following prescription :—

Inf. digital, ℥j ;
Liq. potassæ, ℥xx ;
Tr. canthar., ℥v ;
Dec. scoparii, ad ℥j.

To be taken three times a day, but not until a wet pack is applied to the loins.

On the 25th—the day before the patient's discharge—the urine was light yellow colour, clear, very acid ; sp. gr. 1023 ; contained no albumen. A flaky deposit, partly soluble on boiling ; looks like mucous and epithelium ; 16½ ounces passed in the twenty-four hours.

On the 26th the patient was discharged.

On January 13, 1882—that is, about six months after his discharge—he was brought to the hospital to see Dr. Eustace Smith, and six small yellow-brown concretions were produced which he had passed on January 3 with much pain. Since he left the hospital he had passed no blood, except a little on one occasion.

The calculi were shown to consist of uric acid by dissolving completely in caustic potash, and giving the murexide reaction. They were about the size of a large pin's head.

Transactions of Societies.

HARVEIAN SOCIETY OF LONDON.

THURSDAY, JANUARY 5TH.

The President, HENRY POWER, F.R.C.S., in the Chair.

Mr. FIELD read

SOME CASES OF REMOVAL OF OSSEOUS TUMOURS FROM THE AUDITORY CANAL.

He related several cases in which he had operated successfully on ivory exostoses (hyperostoses) by means of the American dental engine, drilling through the growth, thus making a permanent opening. In other cases of pedunculated osseous tumours, exostoses, made up of soft bone, he usually removed them with stump forceps, such as are used by dentists for the upper jaw. In all cases the patients regained their hearing satisfactorily. In the case of multiple growths, operations were, as a rule, unnecessary, for a triangular space was left between the apices of the tumours, which, growing from opposite sides of the canal, became wedged together, so that the aperture was not completely closed up. Five patients with ivory exostoses were accustomed to bathe regularly in the sea. From this fact he was led to conjecture that this disease, instead of being invariably due to gout, rheumatism, or syphilis, or being influenced thereby, is more often the result of a chronic inflammation of the walls of the external meatus, such as might be produced by sea-bathing, or from the presence of pus in the canal.

Dr. STEPHEN MACKENZIE asked if serious brain symptoms ever followed these operations ?

Dr. BROADBENT mentioned a case of double exostoses, in which severe giddiness and sickness occurred when the mucous membrane was congested.

Dr. CLARKE and the PRESIDENT spoke, and

Mr. FIELD, in reply, said he had never met with a

case in which serious brain symptoms had followed the operation.

Mr. KNOWSLEY THORNTON read a paper on

ENCYSTED DROPSY OF THE PERITONEUM.

The disease is very rare, but he had met with two cases in his hospital practice in the last three months ; and this showed that we must be prepared to diagnose it from other abdominal enlargements, correct diagnosis being all-important in these cases for successful treatment. He alluded to the small amount of information on the subject to be found in either the general or special text-books ; quoted at some length a case in Mr. Spencer Well's work on "Diseases of the Ovaries," which very closely resembled one of his own ; alluded to the opinions of Drs. West and Peaslee, and showed how very misleading the statements of the latter are, the errors arising, in his opinion, from an attempt to generalise from very imperfect data. He pointed out that it is important to distinguish this disease from the much commoner conditions, in which partial collections of fluid occur in the peritoneum, around malignant growths. His own cases were then fully recorded :—

Case 1 was that of a woman of 45, supposed to have an ovarian tumour, which was also supposed to have ruptured into the peritoneum while she was under the author's observation. Suppression of urine led to tapping of the peritoneum, which gave temporary relief ; but she died with uremic symptoms, without further operation. The post-mortem revealed very advanced granular disease of the kidneys, a large spleen, and an encysted dropsy, which had become general by breaking down of adhesions. The ovaries were healthy.

Case 2 was that of a young girl in whose abdomen a doubtful collection of fluid existed. It was a very difficult case for diagnosis, but on the whole the author leaned to the view that it was a case of flaccid broad ligament cyst ; abdominal section showed that it was an encysted dropsy of the peritoneum. The fluid was removed, the sac carefully sponged out, and the incision closed without drainage. The patient made a good recovery, the intestines gradually re-occupying the space where the fluid had been, and when she was last seen there was no appearance of re-accumulation. In concluding his remarks, Mr. Thornton urged the importance of the faithful record of rare cases, and pointed out that the knowledge of this disease was still too limited for it to be possible to lay down rules as to diagnosis. He would accept Peaslee's statement that encysted dropsy of the peritoneum is always preceded, and caused by, peritonitis. The causes of the peritonitis are, however, very various. With regard to treatment, he thought it right to open the abdomen and sponge out the sac in any case in which the condition was diagnosed in a patient free from kidney disease ; drainage was not necessary. He urged the advantage of incision as compared with tapping, and spoke strongly as to the value of Listerism in abdominal section, emphasising his faith by his results in ovariectomy at the Samaritan Hospital in 1881 ; during the year he had had forty-one cases, had not once drained, and had only had two deaths, both occurring in young patients, the subjects of malignant tumours.

Dr. BROADBENT mentioned a case of peritonitis with dropsy limited to the great omentum.

Dr. HARRIS also stated that he had seen a case of localised dropsy following childbirth.

Dr. HAYES said after Mr. Thornton's success he would be encouraged to operate in those cases, though he felt the whole difficulty lay in the diagnosis.

The President spoke, and Mr. Thornton replied.

MEDICO-CHIRURGICAL SOCIETY, EDINBURGH.

This Society met in the Hall of the Society of Arts, 117 George Street, on Wednesday, Jan. 18, 1882, at eight o'clock.

Dr. PATRICK H. WATSON, President, in the chair.

Dr. BYROM BRAMWELL exhibited a patient with A RARE FORM OF CONGENITAL DISPLACEMENT OF THE HEART TO THE RIGHT SIDE,

the apex beat being felt below the right nipple. On the left side, in the normal position of the heart, there was a marked depression. The patient had come under treatment for injury to his right clavicle when the displacement was detected.

A CASE OF CAROTID ANEURISM.

Dr. BRAMWELL also showed a patient, æt. 70, with the following interesting history. Some twenty years ago the patient had fallen out of a cart, the wheel of which had gone over his neck. A swelling soon made its appearance over the left carotid artery, which was considered, by the surgeon who first saw the case, to be an aneurism. The patient was seen by several surgeons in Dublin who entertained the same opinion of its nature, the patient being shown as a pathological curiosity. In Dublin he entered one of the hospitals as an in-patient, but on learning one evening that he was to be operated on next morning he tried to get his clothes to leave, but failing to obtain them he managed to get to a window, where his cries to be rescued attracted the notice of a priest and a policeman, by whose assistance he was removed from the hospital. After leaving the hospital the tumour has become smaller, but still can be easily felt in the neck, more or less connected with the carotid artery. Dr. Bramwell was of opinion that the earlier diagnosis was correct, and that the case presented one of spontaneous cure.

Dr. BRAMWELL then exhibited two photographs of the hand of a patient more or less contracted from injury to the nerves.

Mr. CHIENE exhibited

A RED ELASTIC CATHETER

which he had removed from the bladder of a patient with a lithotrite under the following circumstances: The patient was under the care of Dr. John Wyllie suffering from typhoid fever, and who, in passing the catheter on himself, felt it suddenly slip from him and disappear into his bladder. The catheter had been, for twenty days, in the patient's bladder when it was successfully removed by Mr. Chiene.

Dr. GRAHAM BROWN exhibited a uterus which had been removed for malignant disease of the fundus followed by the usual result—death.

Dr. P. H. WATSON then read his

VALEDICTORY ADDRESS,

which was characterised as usual by Dr. Watson's elegance of diction. After mentioning the sad losses which the Society had experienced during the last two years by the deaths of such men as Sanders, Handyside, Wood, and Sharpey, and after paying a just tribute to the merits of each, Dr. Watson gave a most interesting account of the work done in the Society during the two years of his presidency. Judging from the statements made, the Society must be congratulated on the activity of its Fellows and on the good and permanent work done, none of the papers read bearing the impress of pure compilation, and the *puff oblique* which far too frequently is apparent in many medical societies.

At the conclusion of the address, a hearty vote of thanks was cordially given. Dr. George Balfour took his seat as president.

Owing to the lateness of the hour, Professor Fraser's paper on "A Case of Diabetic Coma with Lipæmia" was deferred to a future meeting of the Society.

Special.

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

At the Academie de Medicine, a letter was read from the Minister of Public Instruction, in which M. Paul Bert requested the assistance of that body in drawing up a report on the number of savants who met with death in prosecuting scientific researches, with a view of according to their widows or to their relatives immediately dependent upon them a pension.

NON-RESTRAINT IN INSANITY.—M. Foville gave an account of a visit he had made to the Scotch Lunatic Asylums, and admired the non-restraint system which was applied as far as possible, but as regards France, he did not think the moment opportune to adopt a similar system, unless in a very limited measure. But it is possible that in some or other this system will provoke partial imitations which will contribute indirectly to the amelioration of the condition of the insane in other countries.

THE DIAGNOSIS OF DIABETES.—M. Magitot read a memoir upon the diagnostic value of alveolar periostitis in diabetes, which he terminated by the following conclusions: 1. The examination of the mouth furnishes a constant sign to the diagnosis of diabetes. 2. This sign consists in a lesion of the alveolar border, known as alveolar osteo-periostitis. 3. This manifestation of diabetes which belongs to the *début* of the disease persists throughout its whole course. 4. This alveolar affection is characterised in its first period by a deviation of the teeth; in the second by their *ébranlement*, and alveolar catarrh; and in its third stage the teeth fall. Gangrene of the gums followed by osseous absorption is observed, when the diabetes should terminate fatally.

LUMBAR COLOTOMY.—The last two or three meetings of the Société de Chirurgie have been occupied with a discussion on the superiority of lumbar colotomy over the same operation practised in the iliac region. M. Trélat opened the discussion and insisted that the advantages were all on the side of the lumbar operation. This opinion was fully endorsed by M. Tillaux, who considered it to be the only resource in cancer of the rectum, but it was especially beneficial in non-cancerous stricture. He cited the case of a young man who entered his service for a stricture of the rectum, caused by inflammation of the bowels. The stricture was so pronounced that the finger could not be introduced. He thought of performing Amussat's operation. He performed lumbar colotomy and the patient has, ever since, done well. M. Després never had the occasion to practise an artificial anus; he never met with inaccessible cancers, and by pushing the finger as far as possible into the rectum, he has always been able to reach, even beyond the stricture. Lately, he was called to the country to see a patient suffering from obstruction, the result of cancer; he introduced his finger, and afterwards the whole hand, and by this means he succeeded in giving exit to a quantity of gas and fecal matter. He could not understand why a patient who is condemned to die, should be compelled to run the risk of an operation, when he could be eased otherwise. Dilatation succeeds always with time and patience. M. Labbé had already pleaded the cause of lumbar colotomy before the Academy, and more than ever he was convinced of the utility of the operation. He was very much astonished that M. Després, in a long career of surgical practice, had never met with a rectum sufficiently narrow as to necessitate colotomy, often, it was true, accidents could be remedied by linear rectotomy, but there are cases where colotomy is indispensable. In cases of cancers, extirpation, if it were possible, was the first thing to be done, in default he considered that lumbar colotomy, which he much preferred to iliac colotomy, should be performed. M. Verneuil considered that linear rectotomy was superior to every other method. In any case it possessed equal advantages with the operations of Litté and Callisen. An obstacle placed high up would naturally necessitate the operation of artificial anus, unless the patient be cachectic, in which case he dies, for the operation should be done as early as possible to ensure success, a fact which the English surgeons bear in mind. This operation should not be attempted unless there were present, accidents due to retention, but it is important to distinguish between the symptoms due to the presence of the tumour, and those due to retention. As to the method, he believed that of Litté was the easiest, while in fat persons that of Callisen might give place to infiltration of fecal matter. In concluding his remarks M. Verneuil believed that when possible linear rectotomy was superior to all. M. Pozzi called to mind a case of his in which, contrary to the opinion expressed by M. Després, all attempts at dilatation failed. M. Trélat ended the subject by replying to M. Després who pretended that he had never occasion to practise colotomy. Such an assertion was worthless, as what never happened might occur to-morrow or next day. After all, when with the finger or with dilating instruments, a way has been opened to the fecal matters, it affords but momentary ease for the operation must be recommenced, and the patient is often exposed to hæmorrhages, tearing, and even the peritonæum has been opened. Thus, one must never say I will never make an artificial anus, there are cases in which it is indicated.

FEVER is reported to be so seriously prevalent in the West Rhondda district, Wales, that the medical officer has advised the closing of all schools, and even places of worship, for the present.

THE "MEDICAL PRESS AND CIRCULAR" REPORT
ON THE SMOKE ABATEMENT EXHIBITION.

No. II.

To the list of smoke-consuming grates described in our last two others should be added.

Mr. Thomas Nash, of Great Dover Street, exhibits a Patent Register Stove, which is so far smoke-consuming that (the inventor says) the chimney never requires sweeping. It is cheap.

Messrs. Feetham and Co. exhibit their "Hurst" grate. This is described below.

Mr. H. Thompson, of Essex Road, Islington, also exhibits an undercooling arrangement. The bars are movable. By means of an iron plate the bars and fire are raised *en masse*, and fresh coal then put in below.

VENTILATING GRATES.—Several of those already adverted to are ventilating grates in addition to their smoke-consuming qualities. Those enumerated below make no pretensions to smoke consumption, but base their claims on their ventilating properties alone. Two defects are common to nearly all those on view. 1. That no provision has been made for getting access to the air chamber to clean it out when it becomes foul with dirt, as it inevitably must in time. 2. The air chambers are constructed mostly of iron, which, if it becomes overheated, is likely to deteriorate the air passed over it, and, at any rate, is sure to get rusty very quickly. On mentioning this latter point to one firm, they suggested that the iron could be enamelled, which would partly remove its objectionable features, but this is not done in any of the grates on view.

Messrs. A. Boyd & Son, of New Bond Street, have for inspection a ventilating grate, which appears to possess several advantages over many in use. The body of the grate is made of iron, but is lined to protect it from the direct action of the fire; the back is made zig zag, so as to increase the extent of warming surface in the air chamber. The grate projects well forward, so as to throw the heat well into the room. Lastly, the front of the grate can be unscrewed and removed, so as to clean out the air chamber if required.

The Coalbrookdale Co. also exhibit Whitwell's patent "save all waste" grates. These grates ventilate, fresh air from the outside being warmed by being drawn up a series of vertical tubes at the back, and then passed through a hot-air chamber above the grate, and thence into the apartment. The heat of the warm-air chamber is intensified by carrying the smoke flue through it. The Company claim that the construction of the grate tends to complete combustion of the fuel with little residue, as its name would imply.

Messrs. Perceval and Westmacott, of Bridge Street, S. W., have on view cooking and warming stoves, designed expressly for houses let out in apartments. These stoves appear to possess several points worthy of attention. The principle is the same in both the cooking and warming stoves. In the ordinary chimney opening is placed a hollow iron chamber, with a central recess open in front. In this recess is placed a fire basket, open at the top, but enclosed on the other five sides by as many sets of bars—the interspaces between the bars being very small. The spaces between the bottom bars can be partially or entirely closed so as to regulate the combustion at will. The fire-cage is constructed of such a size as not to completely fill the opening, but to leave a small space all round between it and the hollow iron chamber surrounding it on three of its sides. In the cooking stove this hollow chamber is utilised as a boiler, and by the arrangement adopted cannot become over-heated. The fire is closed above by a hot-plate, with openings for saucepans. The hot-plate deflects the smoke sideways, and compels it to pass upwards through two curved flues, which gradually diminish as they pass upwards. The space between the smoke flues is utilised as an oven. The hot-plate is hinged behind, and can therefore be thrown back if desired. The grate then appears as an ordinary open fire. Being open in front, roasting can always be done. The arrangement seems eminently adapted for persons living in apartments who wish to utilise one fire for both cooking and warming purposes. The stoves can be adapted to burn coal, coke, peat, wood, or gas. A modified form of the above stove is used as an air-warmer. In this form the hollow spaces, which in the cooking stoves form the boiler and ovens, are converted into hot-air chambers, into which fresh air from outside is passed

through a filtering box, containing cotton-wool or other filtering medium. Additional air chambers are formed by curved flues above and below the smoke flues. Several rooms, or a large workshop, can thus be warmed by hot air, in addition to the heat given off by radiation. We are glad to see the inventor prefers ceramic ware for the construction of the air chambers.

Mr. A. B. Verrier, of Weymouth, exhibits the "Comet" Grate, which is manufactured by Messrs. Morgan and Waide, of Queen Street, E. C. The peculiarity of this grate consists in its drawing the fresh air to be warmed down an inlet pipe from the highest part of the building, or it can be taken from the basement if desired. The fresh air is warmed, not by direct contact with the back of the grate fire-basket, but by passing through a chamber, which is itself heated by the smoke flue passing through. The inventor claims that by this grate several rooms can be warmed if wished. In connection with the grate is an exhaust pipe for withdrawing the foul air from the upper part of the room. The fire projects well out, so that it can be seen from all parts of the room. If desired, the patentee states that he is prepared to have the iron gills of the air chamber *enamelled*. The advantages of this are obvious.

Messrs. George Haller and Co., of Lime Street, E. C., exhibit Kohlhofer's Open Fire Grate, in which the same principle is adopted as in the patent hot-air stoves by the same inventor. The smoke flue is divided into two, and the smoke is then made to travel up and down a series of metal pipes until nearly all the heat has been extracted. The pipes are enclosed in a casing within which fresh air passes below and escapes in a warm state above. The arrangement may also be made to warm several rooms. In building, the pipes may be partially concealed in a recess in the wall.

Messrs. Feetham and Co.'s "Hurst" grate is smoke-consuming and ventilating. The fresh air is drawn under the hearth, and then passes up at the back and sides of the grate through gilled chambers, to be delivered into the room at a temperature of 300 deg. F. The grate is wholly constructed of iron. The front is one piece, and is made to unscrew, so as to cleanse the air chambers when necessary.

Messrs. Shorland, of Manchester, exhibit their "school grate." The back of this grate is of iron, and has gills, which project into the chamber, thus increasing the extent of heating surface for the air to pass over. The air (which should always be taken from the outer air), is discharged into the room in a heated state, either at the ceiling level, by taking the hot-air pipe up the chimney, and then perforating the latter, or, in the projecting fire grate, by an aperture either just above or through the mantel. With the first arrangement the greatest amount of heat is most probably gained, but the latter is most easily applied to existing grates. Either of the seven grates just described can be made to warm a room above, or one immediately adjoining, by carrying the hot-air pipes in the required direction. Messrs. E. H. Shorland claim that by one ordinary fire they can warm three rooms, viz., one by direct radiation, and two by hot air.

Capt. Douglas Galton's fire place is ventilating, and, if not smoke less, tends to reduce smoke. The back of the grate is formed of iron lined (on the side next the fire) with fire lumps. A current air passes up between the iron and lining fire lumps, and becoming warm, impinges on the coal above, assisting combustion. The bottom is partly solid. The iron back has projecting flanges into the air chamber to intensify the heat. The warm air passes out near the ceiling.

In the thermhydric fire grate, designed by Mr. Saxon Snell, F.R.I.B.A., and exhibited by Messrs. Potter and Sons, of Oxford Street, the air is mainly warmed by being drawn over hot-water coils, which surround the grate, and being warmed by the fire, assist to warm the room in their turn, by radiation, as well as imparting warmth to the entering fresh air. Mr. Snell claims that the air can never be overheated, as it cannot exceed 212°. This is certainly an advantage, as also is the immunity from any leakage of smoke into the fresh air chamber. The grate is, however, cumbersome and expensive, and few householders will care to have a hot-water boiler and supply, laid on in their ordinary apartments.

With regard to the air supply of some of the ventilating grates described, the makers suggest that the air of the room should be drawn into the air chamber, and then dis-

charged again in a heated state. The advantages, however, of drawing the air from an external source in all cases need only be alluded to, as our readers will see the importance of it at once. Experiments have shown that the temperature of the room remains the same whether the supply be taken from outside, or simply the air of the room be used. The air can be filtered through cotton wool, canvas, muslin, or cocoa-nut fibre if desired.

AUGUSTUS COX.

THE TREATMENT OF SIMPLE CHRONIC CORYZA.

By Dr. LOWENBERG.

Translated from the *Union Medicale*,

By ARCHIBALD HAMILTON JACOB, M.D. Dub., F.R.C.S.I.

(Continued from page 5.)

MODE OF OPERATION, AND INSTRUMENTS.

The use of a means as powerful as the galvanic cautery requires certain precautions, the first of which is to localise its action strictly to the parts which we wish to be affected. This can be done by throwing a light on, and inspecting carefully the field of operation during the time of cauterising. I make use of a frontal reflector which contracts the light of a jet of gas and sends it into the nasal cavity. The nostril is dilated by means of M. Duplay's excellent speculum. I have only applied the following modification to this instrument; the partitions of the ordinary specula are of a thickness which is useless and even obstructive, useless because the valves have only an insignificant pressure to support; obstructive because the field of vision, already so small, is still more contracted by this thickness, I have therefore caused the valves to be made much thinner.

The galvanic cautery ought to be bent to an obtuse angle, the opening of which is at the bottom. We must also avoid allowing the hand to hide the entrance to the nostril. The instrument is introduced cold, and the current is not made to pass until the part of the instrument has to burn has been safely supported against the part to be cauterised. Up to the present, it seems to me that most operators have neglected one point which I believe to be a very important one, that is, to avoid touching the cloison which never, so to speak, participates in the affection, and on which the action of the galvanic cautery is very injurious. I am convinced that certain accidents caused by the operators are due to this part being also burnt. As all the known cauteries have that portion destined to burn at their extremity, it sometimes happens that we touch involuntarily; for example, after a movement of the patient, the septum or other parts which we do not intend to reach. Another inconvenience of the instruments is the following: the enormous temperature produced by the current gives to the cautery a formidable destructive power, and when their ends, which are pointed or edged, are carried to this degree of heat they penetrate the tissues with an astonishing rapidity, and often to a depth greater than we would have wished. I sought a means of getting rid of these inconveniences, and I think I have found it by modifying the construction of the nasal galvanic cauteries. The principal which I have adopted is the following: The part intended to become incandescent is a projecting plate, and not a point more or less fringed out or flattened, far from it; and there is the most important spot, placed, not at the extremity of the cautery, but laterally on one of its branches. In applying the plate of platinum to the diseased portion we avoid the inconveniences which I have just explained. The end not being pointed and not burning we do not risk the involuntary plunging into the tissues. As for the septum it is protected by means of conducting threads which do not carry the plate near them. We could also operate by first introducing the plate a little beyond the parts to be cauterised, to make the current pass at the moment when we commence to extricate the instrument. This last proceeding I have found useful among patients who do not remain quiet, children for example. It is indispensable to have two instruments, one destined for the right nostril which carries the plate to the left, the other which is used for the left side carries it to the right. I use the polyscope of M. Trouvé, an apparatus which closes in

the electricity of one portion by means of the secondary portion of M. Planté and holds it until the moment when it is required. The polyscope, the use of which we cannot too highly recommend, replaces with advantage those complicated batteries for small galvanic caustic operations such as I practise daily on the nose, ears, and pharynx. M. Trouvé alike performs under my directions those of special galvanic cautery. I have employed these new instruments for two years, and have always been able to recommend their use. They seem especially necessary in the cases mentioned above where there are projections on the cloison touching the hypertrophic mucus of the inferior ear. Up to the present it was impossible not to touch the septum in this case, while now my cauteries can be introduced so as to burn the covering of the mucus on one side, and protect the other with the instrument itself.

In fact, it would be necessary to commit veritable imprudences to cause the galvanic cautery to have injurious results, for its use is, as we have said, followed by a very slight reaction. I am brought to the belief that these injuries arise in part from the high temperature (1300°) of the incandescent plate which acts as a powerful antiseptic at the place of application and its surroundings. The galvanic cautery which I have just described can also be used with great advantage to diminish the hypertrophy of tonsils, when one does not wish to resort to sharper instruments, or when it is only necessary to remove the projecting lobes. The protection given by the part which does not carry the plate prevents the uvula, the covering of the palate, and the posterior portion of the pharynx from being burnt. In conclusion, I repeat that the use of the galvanic cautery is the best known mode of treating simple chronic coryza and certain cases of hypertrophy of the tonsils.

“SALUS POPULI SUPREMA LEX.”

WEDNESDAY, JANUARY 25, 1862.

OUR COLLIERIES.

DURING the golden age (brief in its passage) of some half-score years ago, when King Carbon rivalled King Ferrum as to which potentate should claim dominion over the more wealthy subjects, journalists and romancists were not wanting in subjects for their descriptions of the life, manners, and customs among the coal-miners.

To credit the stories then told—and they all had an air of plausibility—the miners feasted themselves on eatables the most sumptuary. Fresh salmon at half-a-crown a pound, Burton beer, brandy and champagne, were some of the items in their own *menu*; while for those interesting pets, their favourite dogs, legs of mutton were the ordinary purveyance. If those times ever existed (and we are far from saying that they did not) the bitter reaction is now but too sadly marked; and we feel bound, in the interests of public health itself, to present to our readers a picture taken from life as it now exists in some colliery villages in the county of Durham.

For some considerable time scarlet fever and kindred maladies have been endemic in and around Durham; and the Local Government Board at last found it expedient to send Dr. Speers upon a roving commission to ascertain its cause. He went, returned and reported, and the report is only what might be expected, bearing in mind the *similia similibus* doctrine, and carrying it to its legitimate conclusions. We find here, as elsewhere, that the three D's follow each other in regular succession—Dirt, Disease, and Death. But not unfrequently, as in the case which we report, a fourth D is found to be an interpolation or concomitant. This D (Drunkenness) is fully as vicious as any of the others, and we have long entertained the opinion that among the working classes in particular, the first D of the series is its prolific parent.

Some dozen miles from the centre of Dr. Speer's late inquiries stands a colliery, which is managed by a resident viewer,—the owner being a country squire. The colliery gives employment to close upon a thousand men and boys, and is, at present, producing a fair "output" of coal; and is reported "good work" among the miners. There is house accommodation proper for about half the number of families employed, and the consequence is that two, and sometimes three families, are crowded into one domicile, which, often consisting of only two rooms, is not well calculated in a sanitary respect to receive them. For fully two hundred of the houses there is not one water-closet provided, so that besides living, sleeping, cooking, eating, washing, "tubbing," dressing, and the other natural calls which must be answered, the homes will not admit of the appellation "happy" if they have each to shelter from a dozen to a score of inhabitants.

A gentleman, who lately "interviewed" the "colliery doctor," asserts that this useful, important, and hard-worked official, informed him that in his daily round of visits he had sometimes seen as many as ten persons inhabiting one room. The pertinent question here arises, How is sleeping accommodation to be provided for such numbers in such a space? It is managed by the "shift" system. The exigencies of pit labour demand always two, and sometimes three or four successive shifts of men in the twenty-four hours. When the pit is in full employment the day shift men "follow in" the night-shift men, and *vice versa*. And the system which is current at work is sometimes followed in the homes; for at this colliery, in its overcrowded parts, the day-shift men lie down in the beds lately vacated by

the night-shift men, and the night-shift men in their turn do the same. In winter time the beds are thus kept warm and comfortable day and night through. But at pay-week ends, when the pit is idle for a day or two, on Sundays, during summer, and at "strike" times, the system must necessarily exhibit its little inconveniences, notwithstanding that other landlords and landladies, namely, those of the public houses, are liberal enough to provide what accommodation they can to meet the emergency. And thus it is that Permissive Bill and Local Option men are not as yet in much request at this colliery.

Such being the house and sleeping accommodation, it may well be supposed that in the matter of closets, earth or water, there will be some deficiency. And so it is. For at least two hundred of the houses there is not one water closet; and what closets there are, as well as the rubbish heaps, are only cleaned out when some neighbouring farmer requires the manure, or has his land prepared to receive it. The consequence is that the wanderer for health and recreation in the neighbouring glens, and the passengers by the railway trains which run daily through the village, continually behold the disgusting exhibition of a local populace discharging nature's functions in every conceivable spot, regardless of the offence to the eyes and nostrils of passers-by.

The water supply of this model rural paradise is equal to its other comforts. For the entire village there is only one "tap;" and it is "laid off" from time to time for a day, or two in succession. The people then have to "requisition" their drink from the public-houses, or from the pools and streams hard by. These fountains do not teem with real *aqua pura*, nor is it reasonable to expect they should, if the reader remembers our narrative just a few sentences back.

Lighting and paving are other requirements in civilised communities. There is neither one nor the other here. The streets and the township road are covered over in summer with thick mould and dust, and in winter and wet weather with mud and slush. The wanderer on business or pleasure here, after dark, runs his chance of stumbling into a rut two feet deep, or of colliding against a stone fully as high. These collisions often cause him to interrupt his walks by throwing him momentarily into a posture, prone, or supine; and they are always disagreeable to gouty toes or "corned" feet. To add to the other pleasures of the situation, the drains have lately become blocked up, so that the effluvia and miasma of the place, within and without, scent with their fragrance the vibrionic air. The requirements of an Act of Parliament demand the appointment of certain health officers—a doctor and nuisance inspector to wit. The services of the former are generally elsewhere "requisitioned" by the latter, and we suppose the ordinary rule is acted up to here. But as the nuisance inspector resides in a seaport town some six miles distant, and is never on view, the doctor's play in the performance will be similarly perfunctory.

Having spun this article already to an inordinate length, and having scarcely entered upon the subject (as this colliery is only a type of many others), we reserve the continuation of our narrative till a future occasion.

THE SALE OF POISONS.

SEVERAL instances of poisoning have lately been the means of awakening public attention to the facilities afforded to would-be criminals by existing regulations with regard to the purchase of poisons. While everyone willingly admits the desirability of so amending the law in this respect as to place impediments in the way of persons seeking to obtain noxious drugs for illegitimate purposes, no one so far has been able to suggest an efficient system of restriction. Nor can we hope to be more successful, although we cannot but think that means might be devised for securing an amount of evidence in connection with every purchase of active poison, that would ensure the certain conviction of any person resolved to convert it to improper uses. It is impossible to deny that avoidance of detection when the consequences of his act shall have become known, is always a first consideration with every murderer; and careful examination of the details of even the least skilfully executed crime of this kind illustrates the anxiety shown to destroy every chance clue to detection of the perpetrator. In those cases where clumsy substitution of coarsely-made poisonous mixtures for ordinary articles of food is the plan adopted, speedy and certain exposure of the guilty party invariably follows; but when instead of this a subtle and deadly poison, infinitesimal quantities of which suffice to bring about a fatal result, is employed, then the question of detection becomes a matter of greater difficulty, and of the first moment to society. Crimes of such a nature can of necessity be committed only by persons of skill and education; and it is they who, as the law at present remains, find but a minimum amount of difficulty in obtaining the means of effecting their intentions. So far as the sale of ordinary commercial poisons, *e.g.*, vermin destroyers, laudanum, acids and the like, is concerned, existing precautions can hardly be multiplied without seriously interfering with the spirit of trade; but it is, no doubt, possible to carry out the instructions given to chemists in a more rigid manner than seems to be the usual custom.

Leaving all cases of this class to be dealt with under existing rules, we desire to advert to the purchase of such articles as aconite, strychnia, and the deadlier alkaloids, by persons supposed to be entitled to their possession in right of professional position. To this assumption we at once take exception. In ordinary practice no medical man can have occasion, for instance, for two grains of aconitia. He would not be likely to prescribe the drug in the form of the alkaloid, and in such cases as he *would* use it, it ought never to be on his own responsibility alone. We feel sure that no single member of the profession would see any hardship in the enactment of a law forbidding him the exercise of rights in this connection, to which also any of the general public could not lay equal claim. To such practitioners as are in the habit of home-dispensing liquors, and tinctures of the more deadly poisons are the only forms requisite for stock purposes; and, we repeat, on the occurrence of any exceptional occasion for administering these drugs in the pure, undiluted form, it should be procured for that occasion only, and then with the cog-

nizance and approval of a brother practitioner. Much as we may wish to avoid the appearance even of imputation, we are compelled to accept the truth of what has more than once been asserted of medicine, that, *viz.*, it puts in the hands of its professors powers of destruction that, to a man under temptation, are irresistible, and which have unfortunately proved to be so more frequently than we care to recall.

It is absolutely necessary to insist that the commission of crimes such as we allude to is facilitated by the conditions under which a medical qualification is held to entitle its holder to the possession of any substance, however deadly its properties, contained in the druggist's warehouse. A first step in the direction of reform is, therefore, to place such restrictions as we have indicated on the purchase of drugs that do not form part of an ordinary dispensing stock. Experience teaches us that the latter would be at once rejected by potential criminals of the educated class, who would, in the presence of the additional precautions we suggest, be seriously hampered in the prosecution of any act of destruction contemplated by them, and by committing which they would bring down irretrievable disgrace on the profession they unworthily represented. The matter is one well worthy of careful consideration, and we commend it to the attention of all interested in the welfare of medicine.

THE DENTAL DIPLOMA TRADE.

We published last week two letters in reference to the protest which we thought it necessary to make against the unrestricted sale of licences in dental surgery to ignorant persons which is now being carried on by the Colleges of Surgeons of Edinburgh and Dublin and the Faculty of Physicians of Glasgow. We revert to the subject now because the broadcast issue of these semi-surgical qualifications to hundreds of persons of the small tradesman class, who are admittedly innocent of even the elements of dental surgery, has come to be a very serious matter indeed for our profession.

We have already stated—and we now repeat—that the three Colleges which we have named are advertising that they will license as dental surgeons any or all of the 2,500 druggists' assistants, hairdressers, tobacconists, and barbers who appear on the "Dental Register," without requiring from them any evidence of study whatsoever. The only tests of fitness required are the readily obtained signatures of one or two unknown persons, and an examination, which we believe to be utterly unreliable as a proof that the candidates have any sound knowledge of dentistry. We charge these three licensing bodies with abusing the trusts confided to them by Parliament for the sake of the money to be made by the fees for these diplomas, and with sacrificing the social and educational status of surgeons generally by letting loose on society, diplomated as dentists, persons utterly unfit for association with even the most lowly general practitioner.

We are not exaggerating the state of the case when we use a phrase so emphatic as this, for the "Dental Register" itself contains the evidence that persons to whom these diplomas are sold are at best nothing better

than druggists' assistants. We have within the last few days been assured by a Licentiate in Dental Surgery of the Irish College of Surgeons that, happening to be in an English provincial town, he sought for the house of a brother licentiate. This residence he found to be a small drug grocery in a back street, and he recognised his brother licentiate in the person of a man whom he met bringing home, in his shirt-sleeves, the dinner beer from the neighbouring public-house!!!

This is the class of dental practitioner to whom the three Colleges are issuing their semi-surgical degrees, and it does not seem to us that the Edinburgh College is in any way excused for engaging in the trade, because, as our correspondent, Mr. Aubrey Husband, informs us, its sales of diplomas are not very large. A College which announces its readiness to sell *ad infinitum* is not entitled to any credit because the buyers are comparatively few.

As regards the course adopted by the Irish College of Surgeons, we cannot at all agree with our correspondent, Mr. O'Duffy. The College deliberately promised to keep its doors open to uneducated candidates until the 1st of August, 1881, and no longer. This promise it communicated to the General Medical Council, and on the faith of the assurance, many of the more respectable practising dentists may have been induced to take out licences who would certainly not have done so if they had anticipated that the College would eventually take to its capacious embrace the "great unwashed" of the "Dental Register."

It is our view that the diploma of every Licentiate and Fellow of the College is degraded by the issue of a Collegiate licence to an ignorant and low-class trader, and that every shilling earned by a licensing body by such a trade is in the nature of professional blood-money, and we hope that, if the *alumni* of these three Colleges, and the respectable dental surgeons of the kingdom, sympathise with us in this view, they will take vigorous steps to stop a trade which we must describe as professionally disreputable.

Notes on Current Topics.

St. Thomas's Hospital.

At a meeting of the Governors of St. Thomas's Hospital, held on Wednesday last, His Royal Highness the Duke of Connaught was elected President of the institution, his election as a Governor having first been rendered necessary. Occasion was taken at the same time to express the hope entertained that the presence of a member of the Royal Family at the head of the administration of the hospital will lead to a renewal of the prosperity once enjoyed by the charity. It certainly cannot be denied that St. Thomas's is sorely in need of being influenced by some external power in this direction, and if the recent action of its governing body is attended with the gratifying result looked for, general satisfaction will be felt in its behalf. It ought, however, to be borne in mind that an unwise expenditure of money was the first cause that operated to the disadvantage of the hospital, which has

never been in so flourishing a condition in its new home that it could be said to justify the outlay on its magnificent house. Now we may perhaps look out for better times, and in this connection it is deserving of note that the experiment of paying wards has been so far successful as to leave a handsome balance on the credit side as the outcome of nine months' working of the system. Even the best friends of the institution can hardly at this moment defend it from the charges that are only half-uttered against it, and which find confirmation in the unfurnished condition of those wards that remain still untenanted. With one great and important hospital slowly but surely advancing to decay, it is impossible to avoid a feeling of anxiety in regard to such others as seem to need improved administration. St. Thomas's has taken a step in the right direction by thus courtng publicity. We trust it may reap substantial rewards for its foresight.

Charity Organisation.

INDISCRIMINATE almsgiving is almost as great an evil as the misery it seeks to alleviate, for oftener than not it does little more than lend assistance to undeserving impostors. Nor is it to be expected that private individuals should at all times distinguish to what extent the objects of their charity are really legitimate recipients of the bounty extended to them, so that the use of an association whose officers are specially deputed to investigate the claims of applicants for assistance, is apparent. We have received the twelfth annual report of the Lambeth branch of the Charity Organisation Society, and from it may be gathered the extent and value of the labours performed by it, and the real relief afforded to persons who are reduced to want by causes not due to their own carelessness, but solely through misfortune. An important feature, of recent introduction by the Society, is the establishment of a central agency for supplying information as to convalescent homes, and through which patients discharged from hospitals may be enabled to enjoy the benefits of a short country change before resuming their usual employment. This is a most excellent arrangement, and will commend itself to every hospital physician and surgeon, since it is often a matter of regret to them that the patients under their care possess no means of obtaining such beneficial assistance towards completely recovering health. The Charity Organisation Society is doing much good work, but none more thoroughly worthy than providing the blessings of fresh air and change to convalescent hospital patients.

A Students' Club.

YESTERDAY, Tuesday afternoon, a new building, specially erected for the purpose, in the grounds of the London Hospital, was opened as a student's club and refreshment room. The movement to obtain this convenience originated with the warden, Mr. Munro Scott, who has assiduously followed up the first proposition, and the present building is the result. In it luncheons and dinners will be served daily, and it will also be used as a reading and recreation room; its privileges are open to all members of the hospital on payment of a small annual subscription.

Oleo-Margarine.

A VERY interesting account of the manufacture and constitution of oleo-margarine and of butterine is contained in *Nature* for Jan. 19th. From it we learn that oleo-margarine is obtained from beef-suet by the patented process of M. Mège Mourier. The suet is first of all digested in tanks with tepid water, and having been broken down in a steam "meat-masher," is forced through a fine sieve. It is now melted in tanks, which are very carefully surrounded by water at a temperature of 120° F.; any higher heat destroys the flavour of the oil by promoting its decomposition. The oil is by-and-by well stirred, and then being left, the membranous tissue subsides, the upper contents of the tank consisting of a clear yellow oil, and a film of white oily substance, which latter is skimmed off. The yellow oil is next drawn away and allowed to solidify, when it is submitted to pressure, packed in linen cloths between galvanised iron plates, a temperature of 90° F. being maintained in the press-room. The result is the production of oil which is oleo-margarine, and cakes of stearine which serve for the manufacture of candles. The oleo-margarine is packed in barrels for exportation, or by adding to it 10 per cent. of milk, and churning, it becomes "butterine."

Butterine is really a harmless compound, which differs from natural butter chiefly in the proportion of its soluble and characteristic fats—viz., butyric, capric, &c. The following tables exhibit the composition of the two substances as evidenced by chemical analysis, and they afford a suggestive study:—

	Butter.	"Butterine."			
Water	11·968	11·203			
Solids	88·032	88·797			
	100·000	100·000			
Insoluble fats	{ Olein } { Palmitin } { Stearin } { Arachin } { Myristin }	13·824	24·893		
		51·422	56·298		
		Soluble fats	{ Butyric } { Capric } { Caproin } { Caprylin }	7·432	1·823
				0·192	0·621
5·162	5·162				
Colouring matter	trace	trace			
	88·032	88·797			

The suet yields 34 per cent. of its weight of oleo-margarine, and this latter is worth one shilling per pound. It is exported from America principally to Rotterdam, and being then churned into "butterine," finds its way to the English market.

In the principal foreign cities the rates of mortality per 1000 of the various populations were, according to the latest official weekly returns, as follows:—Bombay 28, Madras 30, Paris 27, Geneva 32, Brussels 22, Amsterdam 20, Rotterdam 25, The Hague 28, Copenhagen 25, Stockholm 21, Christiania 24, St. Petersburg 53, Berlin 24, Hamburg 30, Dresden 32, Breslau 30, Munich 28, Vienna 29, Prague 30, Buda-Pesth 31, Naples 24, Turin 31, New York 32, Brooklyn 24, Philadelphia 21, Baltimore 24. No returns were received from Calcutta, Rome, Venice, Lisbon, and Alexandria.

The South City (Dublin) Dispensary.

WE report to-day, in the Supplement of our Journal, which is devoted to Irish Poor-law medical affairs, the proceedings of the committee of management of this institution upon the resignation by Mr. Croly of his appointment as medical officer thereto. It is very agreeable to us to notice the cordial *bene decessit* which Mr. Croly received from the committee. Twenty years of continuous service, with the entire approbation of his masters, and of the central authority whose duty it is to supervise the working of the dispensary, certainly earned for Mr. Croly the vote of thanks which the committee passed, and we are glad to find that under such circumstances the governors of dispensaries can sometimes be grateful. Mr. Croly has always been an excellent officer of his department; and while we congratulate him on having more lucrative occupation for his time, we condole with the sick poor of the district on losing his services.

Who is to Pay the Doctor?

ACCORDING to the *Standard* of Friday, Jan. 20th, 1892, Mr. S. F. Langham, Deputy-Coroner, held an inquest on the 19th relative to the death of John Manchester, aged 15 years. The following evidence, opening out a very important question of ethics, was adduced:—"Augusta Manchester deposed that the deceased was her son. He was in the employ of a carriage builder, and left home on Monday morning apparently in good health, and went to work. About eleven a.m. witness was suddenly sent for to go to the lad, who had been taken ill while at Messrs. Alford's, carriage builders, Newington Butte, having been sent there on an errand. When she got to him he was in a kind of fit, and quite unconscious. A neighbouring doctor was sent for (Dr. Lamb), who ordered his immediate removal home in a cab, and told witness to come to his surgery at once for some medicine, as the case was most urgent. Upon going to the surgery a few minutes afterwards the medicine was ready, *but the doctor (Dr. Lamb) said she must pay 2s. 6d. for it before he could let her have it.* Witness was in such a state of anxiety about her boy that she never thought about money on leaving home, and as she had not got the 2s. 6d. *he refused to give her the medicine.*—By the Coroner: He told me the medicine my boy needed was of the most expensive kind, and he must have the money first. *I begged of him to let me have one dose for the sake of the boy's life, but he would not. He told me he must insist on my returning home and getting the money.* I thought this very hard, especially as he had told me the case was urgent, and was alarmed at every moment's delay. I then went for Dr. Matcham, but before he came my boy was dead.—Alfred Walder gave evidence as to the symptoms of the boy when he was taken ill.—Mr. A. Matcham, surgeon, Gladstone Street, St. George's Road, deposed to being called to see the deceased, and to life being extinct upon his arrival. From what he could learn he was of opinion that the boy had been suffering from brain affection for some time, and all the symptoms pointed to death being the result of apoplexy.—By the jury: It was a rare thing to find a person so young dying from apoplexy, but witness had seen cases at even an

earlier age.—The Coroner: You have heard what Mrs. Manchester has stated with respect to Dr. Lamb's refusal to supply her with medicine unless she first got the money. Do you think if medicine had been given that the life of the deceased might have been saved?—Witness: From all I can see the case was hopeless from the first.—A verdict of Natural Death was recorded."

Medical men are frequently called to cases of emergency; as a rule they give their services gratuitously. There is no provision for payment in such cases. Is this just? We shall be glad to hear the opinion of some general practitioners on this point.

The Teaching of Aural Surgery.

At a meeting of the Committee, appointed by the Committee of Council of the British Medical Association, to consider and report on "the best means of promoting the study of aural surgery, especially in regard to compulsory examination in this subject by the various examining bodies," held on January 11th, it was announced that the following otological teachers had signified their willingness to join the Committee—viz., Messrs. A. Gardiner Brown, H. H. Clutton, A. E. Cumberbatch, W. R. Dalby, G. P. Field, A. Hensman, W. L. Purves (London), Thomas Barr (Glasgow), J. J. Kirk Duncanson (Edinburgh), A. H. Jacob (Dublin), J. Macfie (Glasgow), and J. A. Nunneley (Leeds). Dr. Urban Pritchard was elected chairman, and Mr. Cresswell Baber honorary secretary of the Committee. The names of numerous other gentlemen, in all parts of the kingdom, interested in otology, were also added to the Committee, on the condition of their consent being obtained. The next meeting will be held at 3 George Street, Hanover Square, London, to-day, Wednesday, January 25th, at 4 p.m. Communications on the subject should be addressed to Cresswell Baber, Esq., M.B., 4 Preston Street, Brighton.

Mr. Spurgeon on Vivisection.

SOME anti-vivisection fanatics appear to have interviewed Mr. Spurgeon. We observe that a paragraph has been going the round of the daily papers expressing "the entire loathing with which the reverend gentleman regards the process by which men of education—or men at all—bring themselves to perform such cruelties." We can hardly see why Mr. Spurgeon should be called upon to "loathe the doings of educated men." Would it not be far better for him to keep to the work of his Tabernacle, and leave educated men to the work of education? There is a good deal of inconsistency apparent in Mr. Spurgeon, as in other men, who persist in meddling with questions they don't understand. Surrounded by his admirers in the Tabernacle, a week or two ago, he boasted before them of having resisted all the temptations of the Parisian shopkeepers, with one single exception, and that was when he was shown a new-fangled rat-trap. This he purchased and brought home with him, and, he added, with considerable gusto, "he hoped the rats would like it." Now it so happens that this French rat-trap is calculated to inflict a good deal of unnecessary cruelty upon Mr. Spurgeon's rats, and in a way that a vivisectionist, with a very ardent desire to try an experiment for the good of mankind, would shrink from inflicting upon a rat.

But perhaps Mr. Spurgeon's "intense loathing" does not extend to rats when they poach upon his manor. Another act of inconsistency we also notice in connection with Mr. Spurgeon and his Orphanage. He very properly set forth, as worthy of imitation in all charity orphanages and similar institutions, a perfectly righteous freedom from the acknowledged evils inflicted on friends of candidates in the way of expense, trouble, and loss of time, and the cruelties in general inflicted by the system of canvassing for letters of admission. There was nothing of the kind in connection with the Spurgeon Orphanage, and for this reason especially it had a strong claim for support on the public. Only a few weeks before this boastful speech was delivered we find Mr. Spurgeon giving every encouragement to the Committee of the Surgical Aid Society, who, it is known, persist in inflicting all the unnecessary fatigue, expense, and loss of time in canvassing for letters upon all applicants for relief; and the reverend gentleman says that, in his opinion, it is in every way for the good of the charity, if not for the unfortunate cripple, who may require a wooden leg or other surgical appliance, that this kind of cruel kindness should be encouraged and continued. Mr. Spurgeon's approving letter has been distributed broadcast, and has, no doubt, made the hearts of the Committee of the Surgical Aid Society more obdurate on this point.

Small-pox in Belfast.

SMALL-POX continues to spread in Belfast, and the deaths each week continue to gradually increase. During last week 9 deaths were registered, the highest number yet recorded since the outbreak commenced. All precautions are being taken by the sanitary officers to limit the spread of the disease, but it is feared that a large number of cases exist which are concealed from the authorities.

Alleged Manslaughter by a Quack.

AFTER successfully evading the police for a week, "Doctor" James, the alleged quack who treated the boy who died of spina bifida, near Naas, has been arrested at Balinglass on the warrant of Dr. Carter, coroner. He is charged with manslaughter. Bail has been refused. The date of the magisterial investigation has not yet been fixed.

"Forged Diplomas."

AT the assizes at Reading, before Justice North, Arthur Augustus Sadgrove surrendered, last week, to his bail on an indictment charging him with unlawfully and wilfully uttering a certain document purporting to be a diploma of the Faculty of Physicians and Surgeons of Glasgow, by producing the same to one Thomas Scott, he then knowing the same to be false; he was further indicted on nine counts for obtaining money by false pretences.

It was alleged that Mr. Sadgrove, whose only qualification was that of Licentiate of Apothecaries' Hall, Dublin, constantly signed certificates, appending M.D. and surgeon to his name. He also put these titles on his door.

The learned judge, after carefully going through the evidence, said he had arrived at the conclusion that it was not sufficient to sustain the charge of false pretences. At

the two interviews which the prisoner had with Mr. Scott not a word was said about money, nor did it appear that the prisoner obtained the situation by anything which he said at the first interview. He obtained it probably by reason of his having been recommended by Mr. Scott as a fit and proper person and from his general repute in the district. But this was not enough. To satisfy the statute it was necessary that the prisoner should have obtained either money or a valuable security, but the situation which, in fact, he did obtain, even on the assumption that it was obtained on the strength of his representations, could not be said to be either one or the other; and the same difficulty was fatal with regard to the second interview, for the statements then made by the prisoner were made directly for the purpose of satisfying inquiries as to his qualification as a surgeon, and were not made with a view to continuing in his employment and receiving money. He therefore directed the jury to acquit the prisoner on the counts in the indictment which related to these charges. As to the charge of forgery which remained, this stood on a different footing, and the jury would have to ask themselves whether they were satisfied by the prosecution that the document shown by the prisoner to Mr. Scott purported to be a diploma, that the prisoner knew it was not a diploma when he said that it was, and if it was not a diploma and the prisoner knew that it was not, whether it was produced by him with intent to defraud. The prisoner was acquitted.

Tuberculosis.

In an exceedingly original and instructive pamphlet ("Tuberculosis." Bailliere, Tindall, & Cox), the president of the Royal College of Veterinary Surgeons, Mr. Fleming, following the views of continental observers, believes in the analogy if not absolute identity of tubercle as met with in man and in cattle. He considers that, to some extent at least, infantile diarrhoea is possibly due to their receiving milk of tuberculous cows. He points out that bovine tuberculosis occurs and prevails under similar circumstances as the same disease in man, viz., in poor localities and in valleys. Bovine tuberculosis is more prevalent than the disease in man. As in man, so in cattle, the disease is hereditary, more frequent in females than in males, and in the young than those more advanced in years. In calves, as in very young children, it is rare; and cows thus affected frequently yield abundant quantities of milk. It is among cattle, as in man, more prevalent in temperate than in cold climates; occurring among those animals for the most part in a chronic form. It is very rarely met with in the sheep and goat. Besides being hereditary, its presence among animals is increased by the plan of breeding in and in. All animals, when inoculated with tuberculosis do not become affected with the same readiness. Dogs show little susceptibility, while rabbits and guinea-pigs have it in a remarkable degree. The disease readily appears in pigs fed with the milk of tuberculous cows. Mankind runs great risks of becoming similarly affected.

THE huge sanatorium at Egham, on which Mr. Holloway, of pill and ointment fame, is said to have already spent £300,000, will probably be opened in May. The institution will be endowed with £50,000.

Hygiene in the Far North.

IN his recently published work "The Land of the Midnight Sun," M. du Chaillu gives much interesting information regarding the habits of the people within the Arctic zone among whom he travelled. Of the Laplander, he says (vol. ii., p. 169), that by the severe training he undergoes from childhood, sleeping on the bare ground or resting against a stone, suffering hunger, and being exposed to great changes in the weather, the Laplander has very great powers of endurance. In summer he follows his herd. He is compelled to go through bogs and swamps, or cross patches of deep, soft snow, to swim or pass rivers swollen by melted snow or the flow from glaciers; often hungry, and obliged to milk a reindeer for subsistence, when he comes to the *kata* he is generally overcome with fatigue, and changing his wet clothes he falls into a deep sleep brought on by sheer exhaustion. In winter he travels over dreary wastes, during violent storms, suffering from hunger and cold—on the watch night and day for bears, wolves, and gluttons.

And what are the effects upon health of such a manner of life? Viewed from a "scientific" standpoint, they ought to be, and doubtless are, disastrous. What they are in fact M. du Chaillu tells his readers, namely, "All this makes the mountain Laplander one of the hardiest of men. Consumption, cancer, chills, fever, affections of the liver and kidneys are unknown." The water is as pure as in granite countries, and the drinking of sour milk prevents many complaints elsewhere common. Acute diseases, however, are common; rheumatism is apparently infrequent, if it occurs at all. The Laps use the fat which comes from cheese as an application to sores and sprains. Measles, small-pox, and ophthalmia are frequent among them. The men and women attain very great age; some upwards of a hundred years. Their food consists chiefly of flesh, they use barley flour for *mush*, unleavened bread and plum pudding. They often add sorrel (*Rumex*) to their milk. They are great drinkers of coffee, inveterate smokers and snuff-takers. The vice of drunkenness, once so prevalent has almost disappeared at home among them, but whenever they go to a town, and can procure spirituous liquors, they generally have a frolic for a day or two. Hygienic rules are little thought of among the Laplanders; and yet a hardy, strong, and healthy people are the Laps.

The Hospital Saturday Fund's Convalescent Home.

A LARGE gathering of working men, delegates and supporters of the Hospital Saturday Fund, took place on Saturday night last, at Exeter Hall, under the presidency of Mr. Samuel Morley, M.P., for the purpose of promoting and inaugurating a Working Man's Convalescent Home, not far from London, and in connection with the Hospital Saturday Fund. An almost unanimous opinion was expressed in favour of the movement, since it appears that as great a difficulty in obtaining letters of admission for Convalescent Homes has been experienced by the Hospital Saturday Fund as by the Hospital Sunday Fund. The system of begging for letters grows more nauseous and more distasteful in connection with charitable work of all kinds. Many letters were read from employers of

labour and benevolent gentlemen promising substantial help and support, and there appears every prospect of a sufficient sum of money being collected to carry the project into effect during the ensuing summer. As usual, some few persons present expressed fears that the movement might damage the prospects of the Hospital Saturday Fund, but the chairman and the majority most decidedly entertained a very different opinion. Indeed, the working classes can hardly, as yet, be said to have earnestly put forth their strength in the promotion of the Hospital Saturday Fund. If it is considered that the aggregate receipts of the wage-earning classes amount to no less a sum than four hundred millions per annum, and that of this sum, that at least one quarter of it is expended upon beer, tobacco, and things that could easily be dispensed with, it will surely be no privation on the part of any working man who acknowledges the importance of self-reliance in sickness as in health, to deny himself half a pint of beer or half an ounce of tobacco less a week that he may have the satisfaction of assisting in a work likely either to benefit himself or some other member of his family some time or other. We wish success to the project of a Working Man's Convalescent Home, and trust the committee may take a leaf out of the economically-managed Home established by Mrs. Gladstone.

Society of Medical Officers of Health, Dublin.

THE annual dinner of this Society took place on Saturday last, at the Shelbourne Hotel, Dublin. Dr. Darby, F.R.C.S.L., President, presided. The dinner was an excellent one. After the usual loyal toasts had been given and cordially responded to, the President proposed the toast of the "Colleges of Physicians and Surgeons." Dr. Chaplin, President of the Royal College of Surgeons, Ireland, responded, and then proposed the "Health of the President of the Society, Dr. Darby," who, he said, was always distinguished for the position which he held in his profession, and the honour and credit of which he invariably upheld. The President replied in happy terms. He felt complimented by being elected to the presidential chair of a society calculated to do so much public good. The next toast was that of the "Medical Societies," to which Dr. Kidd, President of the Irish Branch of the British Medical Association, Dr. Banks, President of the Irish Medical Association, and Dr. Byrne, President of the Obstetrical Society, responded in excellent speeches. The toast of "The Visitors" was well responded to by Sir George B. Owens, M.D., on the part of the medical guests, and by Mr. George Moyers, LL.D., ex-Lord Mayor, on the part of the lay visitors. The toast of "Dr. Pollock's (Secretary) Health" was received with applause, and was ably replied to by that gentleman. The final toast was the "Health of Dr. C. A. Cameron," who for the last two years had been the President of the Society. Excellent music was discoursed during the evening by Drs. Duffey, Jacob, Power, O'Donoghue, Moyers, and Mr. William Armstrong.

It is announced that Lord Coleridge will make a contribution to the literature of vivisection in the February number of the *Fortnightly Review*.

An Hospital Ambulance for London.

A MEETING will be held early in February for the purpose of considering the proposal to introduce a general hospital ambulance system throughout the metropolis. The Duke of Cambridge, as President of the London Hospital, has kindly consented to preside, and it is hoped that most of the leading hospital representatives will be present. The ambulance waggon recently presented to the London Hospital by Mr. Crossman will be exhibited upon the occasion, and its advantages pointed out by Dr. Howard, of New York, who will also give a description of the ambulance system as at present in practice in New York.

The "Reuben Harvey Memorial" Fund.

THE committee appointed to raise this fund and to establish a memorial to the late Dr. Reuben J. Harvey met at the King and Queen's College of Physicians, Kildare Street, Dublin, on Monday afternoon, the 16th inst., Dr. Gordon in the chair. The honorary treasurer, Dr. G. F. Duffey, reported that subscriptions to the amount of £150 had been already received or promised.

Dublin Hospital Sunday.

THE total amount obtained by the collections last November for this fund amount to £4,066 8s. 7d., which, contrary to expectation, shows an increase of some £16 as compared with the return for 1880. As contrasted with 1879 there was, however, a deficiency of £278. Each charity which participates in the fund collected is assisted (1) according to the amount of voluntary contributions received by it, and (2) by the number of beds utilised. Among the donations was one which may be specially mentioned—viz., a sum of £48, being the proceeds of a football match, played by the Irish Rugby Football Union on the 12th of last November.

A FAMILY at Northampton has been attacked with symptoms of irritant poisoning, after partaking of tinned tongue.

THE Duke of Cambridge will preside at the annual dinner of the University College Hospital, at the Langham Hotel, on February 15.

DR. F. A. MAHOMED and Mr. C. J. Symonds have been elected Assistant-Physician and Assistant-Surgeon respectively on the staff of Guy's Hospital.

THE Duke of Connaught has consented to take the chair at the annual festival of the Hospital for Sick Children Great Ormond Street, at Willis's Rooms, on March 8.

THE most recent returns show that diphtheria is still alarmingly prevalent in Paris, Berlin, and New York. In either city the mortality from this disease is considerably greater than in Great Britain and Ireland combined.

UNDER the will of the late Mr. John Pendlebury, three of the medical charities of Manchester receive magnificent legacies. The Royal Infirmary and the Salford Royal

Hospital and Dispensary become possessed of £20,000 each, and the Children's Hospital £10,000.

A COURSE of eleven lectures on the Mechanism of the Senses is now in course of delivery at the Royal Institution, by Professor McKendrick, the new Fullerian Professor. The first lecture was delivered on the 17th inst.

A NEW wing and chapel added to the Margate Sea Bathing Infirmary by Sir Erasmus Wilson, at a cost of nearly £30,000, will shortly be opened by the Prince and Princess of Wales. The chapel is an exquisite building, containing about £2,000 worth of stained glass.

DEPUTY SURGEON-GENERAL H. T. READE, V.C., has been compelled through failing health, to resign the appointment of principal medical officer to the forces at Barbadoes, where he had served through the recent terrible scourge of yellow fever.

A CONTEMPORARY informs us that, in the city of Brussels, whenever a birth is registered, the registrar hands to the parent gratuitously, a little pamphlet of five pages containing short and plain directions for the management of children. In Paris, where the mortality amongst children is enormous, it is proposed to introduce a similar practice.

THE annual meeting of the Dublin branch of the British Medical Association will take place on Wednesday next, permission having been granted to hold the meeting and subsequent dinner in the halls of the King and Queen's College of Physicians. Several members of Parliament, and other influential persons, have been invited to the dinner. At the general meeting, at 4 o'clock, Dr. Kidd, the President-nominate, will deliver an address on Medical Education—a subject to which, as is well known, he has given much attention, and a very important and satisfactory report on the notification of infectious diseases will be submitted by the council.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1000 of their population were—Leicester 14, Norwich 16, Bradford and Derby 17, Huddersfield and Halifax 18, Sunderland and Portsmouth 19, Bristol, Plymouth, and Edinburgh 20, Birmingham and Bolton 21, Sheffield, Hull, Birkenhead, and Cardiff 22, London and Leeds 23, Newcastle-on-Tyne, Salford, Liverpool 25, Oldham 26, Blackburn, Glasgow, and Nottingham 27, Manchester 28, Wolverhampton and Brighton 31, Preston 34, Dublin 35.

THE highest death-rates recorded in the large towns last week from diseases of the zymotic class, were, per 1000 of the population—4.6 in Hull from scarlet fever, 3.3 in Brighton, and 2.4 in Cardiff; from whooping-cough 3.4 in Wolverhampton, 2.8 in Salford, and 2.4 in Brighton; from measles 3.2 in Preston, 2.5 in Blackburn, and 2.4 in Brighton; and from "fever," 1.6 in Preston, and 1.2 in Cardiff. In Hull 14 more fatal cases of scarlet fever were recorded, raising the number re-

corded within this borough since the beginning of July last to 675. The 34 deaths from diphtheria included 14 in London, 12 in Portsmouth, and 4 in Glasgow. Small-pox caused 24 more deaths in London and its suburban districts, 1 in Brighton, 1 in Nottingham, 1 in Bolton, 1 in Leeds, and 1 in Hull.

THE Coroner for the borough of Wigan (Mr. L. R. Rowbottom) held lately a couple of inquests on children which had died from convulsions caused by improper feeding. He opportunely called attention to the feeding of infants entrusted to nurses, whilst their mothers worked in the mill, and stated that, according to medical testimony, this reprehensible practice most likely accounted for the high death-rate of children under one year in this district. Mr. Rowbottom is a legal coroner, but is wont to pay the highest respect to the evidence and views of members of the medical profession. Were his example more generally followed, much of the existing opposition to lawyers as coroners would pass away.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

SURGICAL ACHIEVEMENT.—The following is current in medical circles in Scotland, as having occurred in a civilised and highly educated country, and illustrates the errors which are possible in the best hands, but which are never published. Surgeon ——— is attending a female in whom "obstruction of the bowels" is diagnosed. He feels "the lumps." He calls in first one prominent physician, and then another; injections, &c., are resorted to, but to no effect. Thereupon he calls in a distinguished surgeon, who, of course, operates. The abdomen is opened; the woman dies; and post-mortem examination reveals—nothing whatever. "Paralysis of the bowels" is then the explanation of the condition demanding operation! This is not quite so good as the unsuccessful case of ovariectomy in which the post-mortem pathological appearances resolved themselves into—a huge pair of scissors! There is really too much operating, and he is the best surgeon who knows when, and why to operate, and not he who is alone dexterous.

DEATH OF DR. ROBERT PINKERTON.—We much regret to announce the death of Dr. Robert Pinkerton of Glasgow, at the early age of 32. Dr. Pinkerton, we understand, was ill but for one week, the cause of death being typhlitis. Dr. Pinkerton was one of Lord Blantyre's surgeons during the Russo-Turkish war, and was understood to have been an excellent surgeon. Much sympathy is felt for his bereaved mother who survives him.

ANDERSON'S COLLEGE, GLASGOW.—DISTRIBUTION OF PRIZES BY DR. LYON PLAYFAIR.—On the 19th inst. the Right Honourable Lyon Playfair, M.P. distributed the Queen's prizes and certificates awarded by the Science and Art Department, South Kensington, to the successful pupils in the evening Science Class Department of Anderson's College, Glasgow. In the course of his address the right honourable gentleman referred to his early association with Anderson's College, where, forty-five years ago, then a young clerk in the city, he began to attend lectures on science. He referred in terms of appreciation to his master in science, Thomas Graham, and his College companions, David Livingstone, Young, of Kelly, Dr. Stenhouse, and Sir Andrew Ramsay.

His address was very interesting, and was listened to with much pleasure.

OUTBREAK OF TYPHOID FEVER IN EDINBURGH.—An outbreak of typhoid fever which threatens to become epidemic has occurred in the Morningside and St. Leonard's districts of Edinburgh. In the first-mentioned district there are at least fifteen families, representing twenty persons suffering from the disease, which it is believed has been produced and spread by impure milk. A dairy-keeper in the neighbourhood is said to have supplied milk to all or nearly all the families afflicted by the disease, and he got his supply of milk from a farm close by. It is supposed that the farmer had used water taken from a burn which passes through the farm for the purpose of cleansing his pitchers and other utensils, and that the impurities of the burn affected the milk, by which the disease is believed to have been propagated. In the St. Leonard's district the outbreak has assumed much greater proportions. There is scarcely a street or terrace in which there are not several cases, and these of a generally severe type. The cause of the epidemic in this district has not been ascertained, but it is also supposed to have arisen from infected milk. Dr. Littlejohn, the medical officer of health for the city, is making investigations into the causes of the outbreaks.

A WINDFALL TO THE UNIVERSITY OF ABERDEEN.—As announced in our last, Sir Erasmus Wilson, LL.D., F.R.S., President of the Royal College of Surgeons of England, has intimated, through Professor Pirrie, his intention to present £10,000 to the University of Aberdeen, for the purpose of founding and endowing a chair of Pathological Anatomy there. In this communication, Sir E. Wilson states that he makes this gift to the University because of the fact that his father was a student at Aberdeen, and as a recognition of the honour which the University had been pleased to confer on the donor in granting him the distinguished degree of LL.D. Some men surely value these titles highly.

EDINBURGH EYE INFIRMARY.—The annual meeting of the subscribers to this institution was held last Friday, when Mr. A. P. Purves, W.S., treasurer and secretary, submitted the report of the managers, which stated that since the re-opening of the charity, twenty-nine years ago, 26,130 individuals had applied for advice, and of these 397 had been accommodated in the house for longer or shorter periods. During last year the applicants numbered 954. A large proportion of the cases were of a severe character, many of them having been for some time under previous treatment. It appeared from the accounts that the income for the year amounted to £108 1s. 7½d. and the payments to £67 6s. 9½d.

ACCIDENT TO THE PRESIDENT OF THE COLLEGE OF PHYSICIANS.—We regret to learn that Dr. D. R. Haldane, the President of the College of Physicians, Edinburgh, has lately met with a severe accident, in which he broke his leg. Dr. Haldane was to have lectured last Saturday week before the Health Society, but was prevented, owing to his accident. We are glad to hear, however, that Dr. Haldane is progressing favourably.

THE REPORTING OF INFECTIOUS DISEASES, EDINBURGH.—At a meeting of the Public Health Committee, last week, the Medical Officer of Health submitted a statement of the expenses incurred for the half-year ending December last in connection with the working of section 208 of the Edinburgh Municipal and Police Act of 1879, by which medical men in the city are required, under a penalty, to give notice to the Medical Officer of Health of all cases of infectious diseases coming within their practice. For each case reported and verified a sum of 2s. 6d. is allowed. The amount was £224 7s. 6d., which represented reports of 1,795 cases. It appeared that reports had been sent in by 130 medical men, the number received from each ranging from 1 to 99 cases.

Correspondence.

FEES FOR EXPERT MEDICAL EVIDENCE.

TUFNELL *versus* THE DALKEY COMMISSIONERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As the newspaper reports of this case have differed in some respects, I deem it right for the information of my professional brethren to give the full particulars, in order that they may take such steps hereafter as they may deem necessary when dealing with public bodies, who in their time of trouble are only too glad to get assistance, and subsequently endeavour to shirk their obligations.

In April, 1879, the Dalkey Commissioners were brought into the Queen's Bench by the late Sir Richard McDonnell, of Sorrento House, and Mr. Musgrave, of Pilot View, Dalkey, upon traverse for injury and depreciation likely to occur to their respective properties from the proposed drainage of the public sewers into Dalkey Sound.

Dr. Cameron, the city analyst, and I, were engaged by Messrs. Casey and Clay, the solicitors for the Commissioners, to act as experts upon their behalf, and we discharged these duties most conscientiously and thoroughly both in and out of court. We received our instructions from Mr. Sanders, the conducting clerk of Messrs. Casey and Clay, upon the 21st of April, 1879, and devoted a large portion of the 23rd in determining to precision (by means of a coloured fluid) the exact course that would be taken by sewage, of the similar specific gravity, delivered at the same depths and at the same spots.

For this service, providing materials, boat and boatmen, I charged the Commissioners £5 5s.

Upon the 28th, I received instructions from Messrs. Casey and Clay to attend at the Court of Queen's Bench, the case having been "Listed." I did so in the morning and afternoon, and for each attendance charged the fee of one guinea.

Upon the 29th, I went to the Four Courts morning and afternoon (the case being expected to be at hearing every hour), and again charged one guinea for each attendance.

Upon the 30th of April the case was called on, and continued for four days, during each of which I was almost continuously in court, with the exception of the 2nd of May, when I was engaged for some hours in conducting experiments at Booterstown in connection with the delivery of sewage there. For each of these days I charged five guineas, making a total of £30 9s. for the combined services rendered to the Commissioners, and in reference to the same, wrote to the Chairman to say that, in consideration of having a residence myself in the township, I would be happy to accept a cheque for twenty guineas for the whole.

From that time (though frequently applying for a discharge of their liabilities to the Commissioners), I could get no satisfactory reply, and it was only after I had put the case into the hands of a solicitor that an answer was given in the form of an offer of ten guineas, just half the amount.

I need hardly say that, after this insult, I had no course but to bring them before the Recorder, who at once gave an order for the full sum claimed, with costs. The case was defended by counsel upon the part of the Commissioners, who sought to establish that the charges were excessive, and that I had not been *directly* employed by the Board. To neither of these pleas would the Recorder listen. The charges, he considered, were perfectly fair (and even moderate for the services performed), and thoroughly established by the case of Ryan *v.* Dolan, which I transmit for your perusal, and which you will lay before your readers much better than I should. As for the pretext that the Commissioners had not personally engaged my services, the Recorder held that the solicitors conducting the case for the Commissioners having engaged Dr. Cameron and myself, they were, of course, bound by their acts.

I have, I fear, trespassed too much upon your pages, but, the case being one that may be of use to your readers, I have thought it better to give the full details.

I am, yours, &c.,

JOLLIFFE TUFNELL, F.R.C.S.I.

[The issue raised by Mr. Tufnell on behalf of the profession is more important than may appear at first sight. It is whether a medical witness, being called as an expert, is liable to be put off with the statutory fee payable to a professional witness, or

whether, on the contrary, he is legally entitled to a special fee for his opinion and services as an expert. In Mr. Tufnell's case, the Recorder has decided that he is so entitled, and the case of Ryan v. Dolan (Irish Equity Reports, vol vii, page 92) seems to settle the point in favour of the medical witness. In this case, certain physicians attended and remained in court to prove the capacity of the testator of a disputed will. The case was compromised, and a decree made that the taxed costs should be paid out of the assets. The taxing master cut the remuneration which had been agreed on down to the level of the fee named in the Schedule, and maintained that he had no discretion to allow more to be paid. A motion was then made to the court to reverse this decision of the taxing master, and the court granted the motion. The judge, in giving his decision, said, "The only question is, whether the Schedule of fees absolutely binds the taxing officer, in the taxation of costs between solicitor and client, as it certainly does in taxation between party and party. . . . In the case of party and party taxation, the rules are strict necessity, and the Schedule of fees; in the case of solicitor and client the rules are liability to the solicitor, and fair justice to the opposite party. Witnesses may be compelled, upon payment of the fee mentioned in the Schedule, to attend for personal examination, but they cannot, and will not be compelled to remain in court day after day, watching the case and the testimony of other witnesses. . . . I think the officer ought to have exercised a discretion, and, inasmuch as medical witnesses, though obliged to attend for personal examination, are not obliged to attend during the examination of other witnesses, I think it is reasonably proper and legally necessary to pay their extra fees."

We are well pleased that Mr. Tufnell asserted his rights, and we think the principle affirmed will prove valuable as a precedent.—Ed. M. P. and C.]

"GENERAL PRACTITIONERS AND THE MEDICAL COMMISSION."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The funny fellow who coined or invented the phrase, "How not to do it" must have been withal a seer, and must have had within the range of his prevision, the doings of the recent Royal Commission on the Medical Acts, when he delivered himself as above. For *how not to do it* is the only expression that will apply to the labours of the said influential and expensive gathering, unless we attempt in the same way to illustrate its outcome by the parable of the mountain in labour. Directly the Commission was named, I placed myself in communication with its noble Chairman, Earl Camperdown, and I brought under his cognisance certain "peculiar" practices which it was the special business of the Commission to inquire into, if it ever had been intended to make the inquiry thorough and useful. His lordship was sufficiently polite to acknowledge my communication; but there the matter ended, though I kept him supplied from time to time with newspaper and private news, and although I gave him the names of three gentlemen in the profession who could have thrown a flood of light upon the business if they were cited and pressed on oath to "tell the truth, the whole truth, and nothing but the truth." I was not vain enough or egotistical enough to represent that I could myself make any *new* disclosures, but I certainly gave the Chairman of the Commission the names of those who could, and why they were not called is pertinently asked in your question, "If not, why not?" in present issue. Therefore mockery and delusion are words not out of place here.

To expect aid, countenance, or encouragement from the British Medical Association in the matter of Medical Reform is another delusion, for I myself know many gentlemen by name who are described in Churchill's *Medical Directory* as members of the *B.M.A.* and who yet employ any number of unqualified assistants—at least, any number from one to half-a-dozen. In illustration of the above statement, I was lately informed by a candidate for an office under the L.G.B. that his

chief competitor (the man who eventually got the appointment) in canvassing the Poor-law Guardians for votes took occasion to say that as he had three assistants planted in the district he was peculiarly fitted to fulfil by deputy the duties of the appointment. Not one of the three, however, holds a qualification, and one out of the three has never been a recognised or regular medical student at school, hospital, or college for as much as an hour in his whole lifetime.

So much for Royal Commissions, for the L.G.B., the B.M.A., and all their doings in aid of the profession, separately or conjointly. When will the profession aid itself?

I am, Sir, yours truly,

J. O'FLANAGAN.

Houghton-le-Spring, Durham,
18th January, 1882.

Obituary.

CHARLES DELACHEROIS PURDON, M.B.,
F.R.C.S.I.

ON Sunday, the 8th inst., death removed a distinguished practitioner—one holding an honoured name in Belfast—Dr. C. D. Purdon. He succumbed, in his 64th year, after a couple of days' illness, much regretted by the profession and a large circle of friends and acquaintances. Dr. Purdon was the son of Dr. Henry Purdon, who practised as a surgeon in Belfast many years since, and received his medical education at Trinity College, Dublin, where he duly graduated in Arts and Medicine, while two years previously he obtained the Fellowship of the Royal College of Surgeons in Ireland. He proceeded to practise in Belfast, and became medical officer to the Belfast Charitable Society, and, for nearly twenty years, physician to the Deaf and Dumb Institution. He also received the appointment of surgeon under the Factories Acts, and was elected Vice-President of the Ulster Medical Society. Dr. Purdon was connected with various scientific societies, and being possessed of a strong bias in relation to antiquarian subjects, he was well qualified to hold the position of Secretary for Ulster for the Royal Archaeological and Historical Society of Ireland. Of a genial and kind disposition, Dr. Purdon was greatly esteemed, and his loss will be regretted by a large number.

PASS LIST.

Royal College of Surgeons of England.—At meetings of the Court of Examiners on Jan. 17th and 18th, the following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College:—

Bamford, Charles Robert.	Nance, Arthur Stanley.
Basa, Frederick.	Openshaw, Thomas Horrocks.
Batten, Rayner Derry.	Paget, Charles Edward.
Broom, Arthur Robert.	Power, D'Arcy, M.A.Oxon.
Canton, Herbert.	Price, J. A. Parry.
Collins, O. A. Glazier.	Robertson, James, L.R.C.P.Ed.
Ellis, William Gilmore.	Rumboll, Charles Frederic.
Griffiths, Charles Thomas.	Simmons, Herbert Charles.
Heells, Robert, L.S.A.	Stephens, L. E. Walker, L.S.A.
Hendriks, Cecil Morgan.	Stow, Charles Lethbridge.
Jenkins, Edward Johnstone.	Travers, Geoffrey Frederic.
Lawson, G. L. Leath.	Trevor, Edward Tull.
Martin, Joseph Henderson.	Veitch, Quinton Reid.
Mayo, Frank Herbert.	Wallace, Alfred C., L.R.C.P.Lond.
Mears, Frederick Charles.	Willey, Alexander Gascoygne.
Mill, William.	Wright, Richard Searle.

NOTICES TO CORRESPONDENTS.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. These cases

will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

COMPILER.—The exact amount received by the charities of London cannot, of course, be stated, but the most recent and reliable estimation places the aggregate receipts at £4,000,000 per annum.

BRIGHTON.—Only about one-third per cent.

MR. J. SEWELL.—The "Transactions" of the International Medical Congress have been published in four royal octavo volumes, and can be obtained of any medical publisher, either together or separately, at half-a-guinea a volume.

QUALIFICATION FOR IRISH CO. INFIRMARY.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—Would you kindly let me know if the Act has been repealed by which *some* but a Licentiate or Fellow of the Irish College of Surgeons could hold the surgeoncy to an Irish Co. Infirmary, and oblige Yours, &c.,

Jan. 15, 1882.

L.K.Q.C.P.

[Yes, repealed by the 39th and 40th Vic., cap. 40, "11th August, 1876."—See "Irish Medical Directory," page 547.—Ed.]

THE WIDOWS AND ORPHANS OF MEDICAL MEN.—A Quarterly Court of the Directors of the above charitable Society was held on Wednesday, Jan. 11th. The chair was taken by the President, Sir George Burrows, Bart. Five new members were elected, and the deaths of three reported. The applications for grants from fifty-eight widows and nine orphans were approved, and the sum of £1,212 10s. was voted to be distributed according to the respective merits of each case. Two widows, recipients of grants, were announced as dead. There were no fresh applications for grants. The Christmas present of £5 additional to each widow and £2 to each orphan amounted to £820, and had been paid in December last. The working expenses of the quarter were £69 9s. 7d.

SURGEON S.—Not very recently. We are, of course, fully interested in the subject, and will consider all you have to urge in defence of your view.

GREAT WESTERN.—The post is an important one, and is expected to fall to Dr. Gillespie, of St. Thomas's Hospital.

A STUDENT (Leeds).—You must address the Registrar of the General Medical Council, 299 Oxford Street, London, W., respecting the preliminary examination at the Royal College of Surgeons. The examinations for the present term closed last week.

THE SANITARY INSTITUTE OF GREAT BRITAIN.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR.—In the next issue of the *Press* kindly answer the following queries:—

1. Who is the secretary, and where are the offices of the Sanitary Institute?
 2. When and where are its meetings held?
 3. How does one become a member of it?
- Any other information relative to it will be grateful to

R. J. B.

[* The Sanitary Institute of Great Britain and Ireland was established in 1876; the President is His Grace the Duke of Northumberland, the Secretary Mr. E. W. Wallis, and the offices 9 Conduit Street, London, W. Its objects are the advancement of sanitary science and granting of certificates to local surveyors and inspectors of nuisances. Meetings are frequently held for the reading of papers, and for discussion; and a congress and exhibition is held annually in the autumn at some provincial town. The election of members takes place in the usual way, on the proposal and seconding of existing members. Our correspondent should write to the Secretary for a list of members.—Ed.]

MR. WARD.—We have the official Blue Book, "Health of the Navy for 1880," before us, and are bound to admit that the operations of the Contagious Diseases Acts do not show such favourable results as formerly.

DR. CROFT.—The "guinea jaw" may be taken as an illustration of the class of men whom the Dental Act dragged from obscurity into notoriety. However, when qualified members of the medical profession send round hand-bills, we can hardly expect that advertising dentists will fail to utilise our letter-boxes for the poetry of "guinea-jaws."

DR. BRUNKER.—In our next.

ERRATUM—PRINTER'S ERROR.—"Our Services to the Cause of Poor-law Medical Officers." In our last issue, page 54, second column, fourth line, for "A great many of the legitimate claims," &c., read "Jealousy of the legitimate claims of contemporary medical journals has never been one of our failings," &c.

The name of Mr. Chandlee, of the Carmichael School, Dublin, was, in connection with the memorial to the late Dr. Benben Harvey, inadvertently spelled Chandler in our Journal of the 18th.

MEETINGS OF THE SOCIETIES.

HUNTERIAN SOCIETY.—This (Wednesday) evening, at 7.30 p.m., Council Meeting.—8 p.m. Report of the Committee on Mr. Steven's Case of Cerebral Tumour.—Dr. Carrington, "On Cases of Hepatic Abscess associated with Dysentery."—Dr. Turner, "On Miliary Aneurisms from a Case of Cerebral Hemorrhage."

CLINICAL SOCIETY OF LONDON.—Friday, Jan. 27th, at 8.30 p.m., Mr. W. H. Kesteven, "On a Case of Unilateral Xanthopais."—Cases

of Renal Calculus removed by Operation by Mr. Marcus Beck, Mr. Butlin, Dr. Whiphram, and Mr. Haward.

SURGICAL SOCIETY OF IRELAND.—Friday, Jan. 27th, at 8.30 p.m. **ROYAL INSTITUTION.**—Tuesday, Jan. 31st, at 3 p.m., Prof. John G. McKendrick, "On the Mechanism of the Senses."

HARVEIAN SOCIETY.—Thursday, Feb. 2nd, at 8.30 p.m., Mr. Osman Vincent, "Cases of Contraction of the Knee and other Joints."—Dr. Day, "On Headaches in Children."

Vacancies.

Belmullet Union, Binghamstown Dispensary.—Medical Officer. Salary, £100, and £10 as Medical Officer of Health. Election, Feb. 2.

Carnarvonshire and Anglesey Infirmary.—House Surgeon. Acquaintance with the Welsh language is required. Salary, £100, with board. Applications to be sent to the Secretary on or before Feb. 11.

General Hospital, Birmingham.—Assistant Surgeon. Salary, £100 per annum. Applications must be sent to the House Governor on or before Jan. 30.

Granard Union.—Medical Officer for the Finnea Dispensary District. Salary, £100, with £14 additional as Health Officer. Immediate application.

Mercer's Hospital, Dublin.—Resident Medical Officer and Apothecary. Applications to be sent to Mr. James Shaw, at the Hospital. (See Advt.)

Royal Surrey County Hospital.—House Surgeon. Salary, £75, with board. Applications to the Secretary, Town Hall, Guildford, before Jan. 30.

West Herts Infirmary, Hemel Hempstead.—House Surgeon and Dispenser. Salary, £100, with board, &c. Applications to be forwarded to the Secretary on or before Feb. 1.

Appointments.

ADAMS, J. A., M.D., C.M., F.F.P.S.Glas., Extra Surgeon to the Glasgow Royal Infirmary Dispensary.

COWAN, R. H., M.R.C.S., Resident Second Assistant Medical Officer to the Workhouse, Birmingham.

CROUK, H. G., M.B.Camb., M.R.C.S., Medical Officer for the Repton District of the Burton-on-Trent Union.

DAY, E. J., M.M.C.S., F.C.S., Public Analyst for the Borough of Lyme Regis.

FLEMING, C., L.R.C.S.I., L.K.Q.C.P.I., Medical Officer to the Work-sop Union and District, Nottingham.

FLINN, D. E., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer for the Brownhills District of the Cannock Union.

GILL, J., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Welshpool District of the Forden Union.

HEPBURN, W. J., L.K.Q.C.P.I., F.R.C.S.Ed., Visiting Surgeon to the Brabazon Convalescent Home, Bray, co. Dublin.

KNOWLES, H., L.R.C.P.Ed., L.F.P.S.Glas., Medical Officer for No. 4 Salford District of the Salford Union.

PICKERING, C. F., F.R.C.S.E., L.R.C.P.Lond., Surgeon to the Bristol General Hospital.

PRATT, J. D., M.B., House Surgeon to the City of Dublin Hospital.

QUINLAN, F. J. B., M.D.Dub., Consulting Physician to the Dublin Dental Hospital.

SYMONDS, C. J., M.S.Lond., F.R.C.S.E., Assistant Surgeon to Guy's Hospital.

THOMAS, A. H., M.B., C.M., Assistant Medical Superintendent of the Ayrshire District Asylum.

Births.

KESTEVEN.—Jan. 10, at Levuka, Fiji Islands, the wife of Leighton Kesteven, M.R.C.S., Colonial Medical Officer, of a son.

LISTER.—Jan. 19, at Addiscombe Road, Croydon, S.E., the wife of C. H. Lister, M.D., of a daughter, stillborn.

MAYBERRY.—Jan. 6, at Riversdale, co. Kerry, the wife of Francis George Mayberry, M.B., M.Ch. T.C.D., of a daughter.

MOORE.—Jan. 23, at the College, St. Bartholomew's Hospital, London, E.C., the wife of Dr. Norman Moore, Warden of St. Bartholomew's, of a son.

Marriages.

WALSH—CONDON.—Jan. 11, at Newcastle, Waterford, John J. Walsh, M.D., Suirville, to Kathleen Mary, second daughter of the late Thomas W. Condon, Esq., The Mall, Waterford.

SMYTH—SUNDERLAND.—Jan. 18, at St. Peter's Church, Parkstone, Hutton Smyth, M.D., of Poole, Dorset, to Mary S. Sunderland, Swain's Hall Villa, Hereford.

Deaths.

LAWLER.—Jan. 16, at Oldcastle, Meath, John Lawler, M.D., Virginia.

ROBINSON.—Jan. 13, at 20 Waterloo Road, Dublin, Francis Robinson, A.B., T.C.D., L.R.C.S.I., aged 54 years.

TATE.—Jan. 19, suddenly, at 2 Garville Avenue, Rathgar, Robert Tate, M.A., F.R.C.S.I., Surgeon-Major, Army Medical Department, in his 47th year.

PEARCE.—Jan. 8, at Brighton, Ravenhill Pearce, M.D., in his 51st year.

PENNINGTON.—Jan. 13, at Rock House, Ashton-in-Makerfield, James Fairclough Pennington, M.R.C.S., aged 65.

WALDRON.—In December last, in Mexico, Dr. H. C. A. Waldron, eldest son of General Waldron, aged 35.

WRIGHT'S

See Testimonials of entire Medical Press and from leading Dermatologists.

THE PRACTITIONER, of September, 1881, reports a lecture entitled "Recent Advances in the Therapeutics of Diseases of the Skin," by Professor W. A. Jamieson, M.D., F.R.C.P. Ed. The following is an abstract therefrom:—"Itching, which owes its origin to too slow a current of blood, of which the most typical example is that seen in **Eczema**, connected with varicose veins of the leg—but to the same category also many examples of Pruritus Scroti, Labiorum and Ani may be referred—is best relieved by careful flannel bandaging, well applied suspensory bandages, and laxative salts or mineral waters, which unload the rectal veins, by freeing the portal circulation, combined locally with weak tarry lotions, one of the best of which is Wright's **Liquor Carbonis Detergens**, a well-made solution of Coal Tar, suitably diluted."

From **THE LANCET**, Dec. 22nd, 1868: "In our hands it has been a most effective agent in skin diseases, especially of the chronic eczematous class; and one case of psoriasis, which had resisted all other kinds of treatment, speedily got well under the application of the **Liquor Carbonis Detergens**. We esteem it a very valuable addition to our list of skin remedies."

From the **MEDICAL TIMES AND GAZETTE**, January 19th, 1867:—"We have more than once called attention to the value of this remedy in chronic eczema."

From the **BRITISH MEDICAL JOURNAL**, September 22nd, 1871:—"We have tested it and can affirm its value as a detergent agent. We consider the **Liquor** is an article of great utility."

Kept in stock and sold by all Druggists (Wholesale and Retail) throughout the United Kingdom and Colonies.

AGENT FOR DUBLIN—**JOHN EVANS**, Chemist to the Queen and H.R.H. the Prince of Wales, 49 DAWSON STREET.

EVANS'S EXTRACT OF MALT.

PROFESSOR ATTFIELD, Ph. D., F.C.S. (Professor of Chemistry to the Pharmaceutical Society of Great Britain, Nov. 1872), writes:—"Evans's Extract is incomparably more valuable than any preparation of malt hitherto offered to the Public."

PROFESSOR TICHBOENE writes:—"Other preparations of this class which I have examined, on evaporation, yielded only 86 grains of extractive to the fluid ounce, whilst yours contains 101.5 grains."

DR. APOJON writes:—"Of these constituents the most remarkable are those which include Nitrogen, the amount of which is unusually large—reaching, as it does, nearly 5 per cent. The Proteptic compounds in an ounce of it weigh 32.32 grains, and the analogous compounds in an ounce of beef-steak 98.43. Hence, weight for weight, the alimentary value of the Extract is very nearly one-quarter that of the beef-steak. It is, therefore, nutritious in a high degree, and being, no doubt, easy of assimilation, it must constitute a useful supplementary food in cases of debility and weak digestion."

EVANS'S STYPTIC for Checking all Bleedings.

The introduction of this Preparation to the notice of the Profession, arose from the desire expressed by several eminent Physicians and many patients to obtain an efficient Styptic at a moderate price—Ruspin's celebrated Styptic being so costly. The efficacy of the above Styptic has been tested for many years by several Medical Men in a variety of Bleedings, whether from the Nose, Lungs, Stomach or Bowels, and it has met their approval.

THOMAS P. MASON, Esq., M.D., &c., Physician to Mercer's Hospital, writes:—"The Styptic you had the goodness to forward to me, I found highly advantageous in the hemorrhage of phthisis."

P. C. SMYLY, Esq., M.D., &c., Surgeon to the Meath Hospital, writes:—"I have used your Styptic in a great many cases, and find it of the greatest use, in fact, in every instance was equal, if not superior to Ruspin's Styptic. I have found it very successful after the removal of Tonsils,—in Bleeding from the Nose, Lungs, and other organs."

CHRISTOPHER FLEMING, Esq., M.D., &c., Consulting Surgeon to Steven's Hospital, &c., &c., writes:—"It has been most efficient in cases of hæmoptysis, hæmaturia and such class of hæmorrhages; and, as a local remedy in many cases of obstinate epistaxis, it has been of paramount value."

PREPARED ONLY BY

JOHN EVANS, Chemist to the Queen, and H.R.H. the Prince of Wales, &c., 49 DAWSON ST., DUBLIN.

LONDON AGENTS—**BARCLAY & SONS**, Farringdon Street, **SANGER & SONS**, Oxford Street, and

F. NEWBERY & SONS.

WATER-TESTING APPARATUS FOR DETECTING IMPURITIES IN WATER.

(DANCHELL'S PATENT.) Price 10s. 6d. and 21s. each.

Danchell's "Testing Apparatus for Discovering the Presence of Impurities in Water" is a most convenient and portable one.—*Vide* Dyke on the Preliminary Duties of Health Officers.

This is a very handsome case for the study table or carpet bag. It contains the chief chemical tests for qualitative water analysis, and will be found of use by Medical and other men who may have occasion to ascertain in a ready manner whether any of the more actual impurities are present or not in water.—*Vide The Medical Record*, January 29th, 1873.

Manufactured by the Proprietors, **THE LONDON & GENERAL WATER PURIFYING COMPANY (Limited)**.

Patentees also of the **PATENT CISTERN FILTERS**, charged solely with ANIMAL CHARCOAL.

For price, &c., address the Secretary, 157 STRAND, LONDON, W.C. (*Read "Water: its Impurities and Purification," price 6d.*)

The Medical Press & Circular.

RECENT RESEARCHES INTO THE THEORY OF THE LIVING CONTAGIUM, AND THEIR APPLICATION TO THE PREVENTION OF CERTAIN DISEASES IN ANIMALS. (a)

By J. L. W. THUDICHUM, M.D., F.R.C.P., Lond., &c.

ALTHOUGH by the title of the paper I am, happily for myself, confined to recent researches, it will be necessary for me to show you that, and how, they are based upon and cohere with knowledge, which men of science of many nations have produced and stored up, during long periods of time. This knowledge has mainly been obtained by the study of some of the most virulent diseases of animals, with the aid of pathological experiments upon living animals, and could by no means have been obtained without them; and now the species which furnished the hecatombs of victims of disease, and the insignificant number of subjects for experiments, are about to be benefited, or are already benefiting, by the practical results of these studies, to the extent of their being practically free from the liability to at least the most pernicious of contagions and almost certain death, which formerly troubled their prospects.

Some may perhaps think that there was some inconsistency in my discoursing of the theory of contagion, and yet claiming practical results for its application. To be better understood by these persons, who merely follow a common habit of confounding theory with hypothesis, I expressly say that I use the term theory in the genuine Greek sense, as expressing a scientific view, which can be made the basis for action. And I further include, for my present purpose, at least, in the term theory in general, all theoremata, or theoremes, as special cases, and demand for them, as diagnostic conditions, the properties postulated by Galen, namely, that they must be, before

(a) Read before the Chemical and Physics Section of the Society of Arts, Jan. 26th, 1882.

all else, true; further, that they must have a fructiferous influence upon our subject; and lastly, that they must be derived as necessary consequences from the antecedents.

A contagium is a cause of disease, which can be communicated from one individual to another, by some material contact or other only; the term contact here includes not only that immediate contact, in which, e.g., a person nursing a patient comes within the object of his attention, but also in direct contact, such as that to which a washerwoman is liable when she handles the clothes of a sick person. In all cases a contagium is a material particle, or number of particles, which is transferred from a specifically sick person or animal to a healthy person or animal, and produces in the healthy person the same disease as that which affected the person or animal from which it proceeded.

In order to understand how such a contagium can be living, it is necessary to be acquainted with the nature and properties of the smallest organisms occurring in nature. From the consideration of all that is known on this subject, it follows that contagia, which can be distinctly recognised as consisting of a number of similar individuals, belong not to the animal, but to the vegetable kingdom, and therefore the term living contagium would require to be supplemented by the adjective vegetable, if it were not probable that all contagia whatever belong to the world's flora, and not to its fauna. In any case there are no grounds for terming contagia animate, if the condition of animation is allowed to characterise organisms which, in science, are termed animals. In short, contagia, such as we know then, have the characters of the lowest plants.

The term "contagious disease," is, therefore, equivalent to that of "vegetable parasitism." But the equivalence is not absolute.

ITCH.—Itch is contagious. The spider-like (*arachnid*) mite, which is the sole cause of itch (*scabies*), is an animate contagium. It can be transferred from one individual on which it lives, and propagates, and causes eruption, to another healthy one, and cause the same disease of the skin as that found on the body from which it came. It can be killed by chemical agents, and, with its death, all manifestations of disease cease, and all effects heal.

TRICHINIASIS.—Trichiniasis is contagious. The minute worms can be transferred, in a particular manner, from one individual (human or animal) to another, and, by its multiplication, cause a disease which is very similar to an ordinary contagious disease. But there is a great difference in the manner in which the organism of the animal invaded by any of these animal parasitisms reacts against the invading force. And it is by this reaction mainly, which has a remarkable intensity and effect in the case of contagious diseases, that animal parasitisms are distinguished from vegetable.

The reaction of the organism invaded by a vegetable contagium consists in this, that whenever the organism does not actually succumb, it acquires a new property, namely, that of being thereafter either for the length of its entire life, or for longer or shorter periods, so to say, inaccessible to the same, or a very similar, contagium. Thus a person is not very liable to contract yellow fever twice; and small-pox, typhoid fever, or cattle-plague so rarely befall the same individual twice, that one attack is generally considered to protect the survivor from a second one. The condition of body thus acquired is generally described as immunity. This immunity is never produced as a result of animate contagium. A man who has recovered from an attack of itch or trichiniasis, is just as liable to a second infection, or any number of infections by the acarus of scabies or the trichina, as he was before the first attack. But a man who has recovered from the small-pox is not liable at all to contract small-pox again, for a considerable time at least, and even when the contagium, which would give the small-pox to a healthy person, with certainty, is incorporated with his body, it fails to thrive, perishes, and becomes abortive. This undoubted state of immunity from the disease, produced by the disease itself, is one of the most difficult problems of medical science. There is at present no explanation of it for which there could be quoted even the outline of plausibility. It is, however, undoubtedly the result of the reaction of the organism against the contagium and its products. It is a function, not of the contagium, but of the organism invaded.

This immunity exists in a proportion of healthy individuals without their having undergone the effects of the contagion in their proper persons. In such cases the immunity may be inherited, or have been acquired by means which do not present themselves as actual contagion. Or it may have been acquired by a vicarious contagion, which, like cow-pox, exhausts the receptivity of the individual for cow-pox as well as small-pox, or confers the immunity from cow-pox as well as small-pox. For immunity may be the result of an active power acquired, or of the loss of a passive faculty, such as impregnability.

We will now first consider some of the best known vegetable parasitisms or contagia, and their action upon the beings upon which they thrive best and develop their highest power of destructiveness.

VEGETABLE PARASITISMS, OR CONTAGIA.—In New Zealand there lives a common caterpillar, which, when it is nearly full-grown, frequently begins to sicken; a bump appears at its head or neck, and then a fungus sprouts out an inch or two in length. When the fungus has ripe spores, the caterpillar dies. You can see caterpillars of this kind, with fungi attached, exhibited in the Natural History Museum in South Kensington. This is the most grotesque vegetable parasitism of which I know. A single spore introduced into the body of the healthy caterpillar will produce the disease; a mycelium forms in the cavity of the body, and the external growth is only the rapid inflorescence of the hidden growth. In Europe we have a disease of a similar kind, but without the grotesque mushroom sprouting from the surface of the animals, namely, the disease of silkworms, termed muscardine. In this disease the animals die as from an unseen poison, and only by close observation after death is a film of fungoid inflorescence, carrying spores, seen upon their surface. It was the Italian Bassi, who, in 1837, discovered this remarkable fact, upon which all our present knowledge of the subject is based. He cultivated the

spores taken from the skins of silkworms, which had died from the muscardine on moist moss, and was able to reproduce both mycelia and spores, and with the new generation of spores produced out of the body of the silkworms, he was able to reproduce the muscardine in silkworms, either by inoculation under the skin of the worms, or by infecting with the spores, as dust, the air which the worms had to breathe, or by casting the spores on the leaves which the worms had to eat. He thus handled his disease cause so as to show that it was not only a true contagium, but at the same time, a good imitation of a miasm.

These discoveries of Bassi, which at the time when they were made appeared to interest only silk growers, became the starting point for one of the most perfect deductions ever made in science, but doomed to be ignored and to be forgotten; I allude to the pathological researches of Henle, now professor of anatomy at Gottingen, published in 1840. In one article of these researches the theory of living contagium is developed as an hypothesis in all its details, and it is shown that the features of contagious diseases harmonise with the hypothesis in a very remarkable manner.

But the hypothesis lacked the basis of direct experimental evidence. This evidence could not be got out of the consideration of human contagia (it cannot be obtained so now); these had been investigated with rare patience and skill by thousands of physicians, and yet the essence of the nature of virulent disease was as hidden as ever. The method of experiment had to be discovered by the cultivators of another science, that of botany. It was mainly Schwann, the author of the cell theory, who opened new ground, by showing that the phenomena of alcoholic fermentation are connected with the presence and life of elementary minute plants, particularly the yeast plant.

This development was contested by chemists, who in view of the magnitude of the chemical changes induced during fermentation, endeavoured to explain it by analogy more than direct study. And thus it came that what was in itself unexplained, namely, fermentation, was made a type to which diseases were compared, and henceforth contagious fevers were termed zymotic diseases, or *zymoses*.

This was no doubt partly caused by the observation that "the true or metabolic contagia—the contagia which in their respective and specific ways, operate transformingly on the live bodily material which they affect," as Mr. Simon has tersely defined them, produce a great chemical motion in the body, which results in the rapid production of highly oxydisable compounds, and their oxydisation being effected *pari passu*, the temperature of the body is raised more or less above the normal point, and the state called fever, or *pyrexia* is produced. Hence, fermentation and fever become comparable, not only by their chemical course, but also by their potential effect. The purely chemical view of fermentation was mainly elaborated and defended by Liebig, and he made it so probable, that it may be said to have reigned supreme almost to the end of his life. It is only during the last ten years that his opponents have made their views generally prevail, and with results of which we must admire, not only the scientific brilliancy, but also the practical utility. Amongst these, none has worked more arduously and more successfully than Pasteur. During twenty-four years he communicated numerous researches bearing upon alcoholic fermentation. Of these a cardinal one concerned the production by growth, by multiplication, of the yeast cell in artificial nutritive solutions, free from all albuminous substances. From this moment the theory of Liebig had no longer any foundation, and, says Pasteur, the phenomena of fermentation presented themselves as simple phenomena of nutrition, which takes place under exceptional circumstances, of which the strongest and most significant one is this, that air may be excluded from the process. This gave a new impulse and direction to the study of animal

contagia. They reverted to the method of Bassi, and his follower, Audouin, and to the line of thought so well worked out by Henle. In 1863, Davaine resumed his studies of the bacterium of splenic fever of cattle, which Rayer had first shown to be the essential contagium of that disease, by experiments upon living animals, but without any new results. Chauveau, however, by experiments upon contagious matters, such as those of small-pox or cow-pox, endeavoured to uphold the proposition that all contagia are particulate, that all contagiosity is a mixture, such as animal contagia are, resides in its solid particles, and not in its liquid part. After the experiences of the German-French War of 1870, we find the wound-poison ascribed to microscopic organisms by Klebs, and we find the same conviction in this country raised to a general theory, and applied with apparently excellent results to the treatment of all wounds by Lister.

THE BACTERIA OF SPLENIC FEVER.--In 1876, an important progress in the direct appreciation of contagia was made by Koch, then working in the botanical laboratory at Breslau. He sowed the bacteria of splenic fever in inorganic solutions similar to those in which Pasteur had reared yeast plants, and found them grow, develop their germs or spores, and then again grow into bacteria. The new generation of bacteria proved as disastrous to animals as those taken from animals directly. Here, then, was a true or metabolic contagium found out to be an alga-like low plant, to grow in proper media like Bassi's muscardine spores, and to kill as certainly after as before the digression into and propagation in cultivation media.

(To be continued.)

CLINICAL LECTURES ON SYMPTOMS.

Delivered in the Wards of the Hospital.

By FREDERICK T. ROBERTS, M.D., B.S., F.R.C.P.,
Professor of Materia Medica and Therapeutics at University
College; Physician and Professor of Clinical Medicine at
University College Hospital, &c.

LECTURE VI.—ON LOCAL SYMPTOMS.—(Continued.)

IN the last lecture we were engaged with an outline of three main groups of local symptoms, and I now propose to consider the remaining group, namely:—

IV. INTERNAL OBJECTIVE SYMPTOMS.—We have already dealt with the subjective sensations connected with internal parts, but fortunately for us we have not usually to rely upon these for purposes of diagnosis, phenomena of an objective character, which we can recognise for ourselves by the aid of our external senses, being present in the majority of cases in various combinations, thus calling our attention to particular organs or structures, and enabling us, as a rule, after proper investigation to determine the nature of the disease.

It will be well in the first instance, before considering what these phenomena are, to recall to your recollection the principal structures with which you are concerned in relation to internal objective symptoms, as was done in the case of the external symptoms. They may be enumerated according to the following plan:—

1. The alimentary canal and its related organs, including:—

- a. The mouth and its contents.
- b. The throat, with the palate, uvula, and tonsils.
- c. The œsophagus.
- d. The stomach.
- e. The intestines and anus.
- f. The hepatic apparatus, namely, the liver, gall-bladder, and bile-ducts.
- g. The pancreas and its duct.

2. The spleen.

3. The supra-renal capsules.

4. The urinary organs, comprising the kidneys and their pelves, the ureters, the bladder, and the urethra.

5. The female generative organs.

6. The peritoneum; as well as the loose cellular tissue in certain parts of the abdominal cavity, and the deep muscles and bones.

7. The respiratory apparatus, namely:—

- a. The larynx, trachea, and main bronchi.
- b. The lungs and pleuræ.
- c. The diaphragm.

8. The circulatory system, including:—

- a. The heart and pericardium.
- b. The internal vessels, systemic and pulmonary, arterial and venous.

9. The internal absorbent glands and vessels.

10. The nervous system, which comprehends:—

- a. The brain and its membranes.
- b. The spinal cord and its membranes.
- c. Individual nerves, cranial or spinal.
- d. The sympathetic system.

11. Special senses, namely, the eyes, nose, and ears.

Now it is very desirable that you should acquire a concise knowledge of the objective symptoms which you may expect to find in connection with each of these structures; that is, you should not only learn what they are, but try to comprehend their meaning, and how they are produced under different conditions. In order to aid you in this object, I propose in future lectures to discuss the symptoms associated with each important system and organ, but in the meantime it may simplify the matter if I point out that, although varying in their precise character, according to the part affected, they may all be gathered under a few general heads, which I will now briefly indicate.

1. Some of the structures mentioned are easily accessible to the ordinary modes of *objective examination*, and can be, without having recourse to any skilled methods of investigation, seen or felt. This applies, for example, to the mouth and throat, to the anus, and to the external genital organs. The symptoms are thus evident to the senses, and the phenomena presented are similar to several of those mentioned when speaking of external objective symptoms, such as redness or other changes of colour, swelling, deposits on the surface, hæmorrhages, ulcerations, &c. In short, you may often thus directly observe for yourselves the exact morbid conditions present, as you can do in the case of external parts. Again, the odour of the breath, and certain of its other physical characters come under this head, and these may be of much service in diagnosis. Occasionally, internal organs communicate externally, or give other direct evidence of their morbid conditions, as may be illustrated by hernia of various kinds, or the external opening of an internal abscess. This class of symptoms is obviously of considerable value in diagnosis, and they ought to be looked for in every instance in which there is any reason to suspect their presence.

2. A large proportion of objective symptoms depend upon some disorder of one or more *functions* of an organ. If you understand the physiology of organs, you will have no difficulty in comprehending the meaning of many, if not most of their symptoms. The functions disordered may be included under three subdivisions, namely:—(a) *actions or movements*; (b) *secretions and excretions*; and (c) *special*. In some cases these are combined in various ways. Actions are either exaggerated, impaired or checked, or abnormal in character. Secretions and excretions may be excessive in quantity, deficient, or absolutely suppressed; abnormal in quality, either when first formed or from admixture with other materials; or unable to reach their proper destination, being either retained or escaping in some unusual direction. The special functions are variously affected, according to their nature. Mastication, deglutition, articulation, defæcation, and the cardiac movements afford examples of actions, the disorders of which often give rise to more or less prominent symptoms. In the

case of the stomach and intestines, we frequently have to deal with symptoms due to a combination of disorders affecting secretions and normal actions, or either one or the other may alone be involved. The same remark applies to the urinary organs, where we find the urine and micturition deranged together or separately. The liver and pancreas give us illustrations of organs in connection with which symptoms may depend solely on disorders of secretions. Respiration and menstruation are conspicuous instances of special functions which may be disturbed; and the different portions of the nervous system afford a great variety of symptoms due to disordered functions, according to the particular portion of this system which happens to be affected.

3. Another important group of objective symptoms is due to some *abnormal action*. That is, an action occurs which is not a mere disorder of one carried on in the healthy state, but which is altogether new and unusual, being the evidence of some abnormal or morbid condition by which it is excited. Sneezing, hawking, cough, vomiting and retching, are the most striking examples of this class of phenomena, and you are aware that such symptoms are often of much consequence. Certain actions which are associated with some nervous diseases may also be mentioned here.

4. *Hæmorrhages* from internal parts constitute a class of symptoms which demands particular recognition. Such hæmorrhages are frequently of considerable moment, and may be very dangerous in themselves; while they afford signs of the utmost value in the diagnosis of several diseases. The most important are *epistaxis*, or bleeding from the nose; *hæmoptysis* or spitting of blood; *hæmatemesis*, or vomiting of blood, *melæna*, or blood in the stools; *hæmaturia*, or blood in the urine; *menorrhagia*, or excessive bleeding from the female generative organs. The blood may escape spontaneously, or be expelled by some of the actions already mentioned. In certain forms of hæmorrhage it is very apt to become altered in its physical characters, so as not to look like blood, and of this fact it is highly important that you should be aware, as well as of the special characters which the blood presents in each case.

5. Another group of symptoms comprises those which may be included under the head of *discharges*. In addition to blood, which has just been specially considered, various materials are discharged from internal parts of the body in a similar way, that is, either escaping spontaneously, or being driven out by certain actions. They may come away separately, or be mixed with normal discharges, such as the urine. These commonly afford most valuable information, and may also demand direct interference in treatment. They are of very diverse nature, according to whence they come, and what they depend upon; and without attempting to give a complete list, it will suffice to mention as prominent examples, the materials expelled from the stomach, such as gases, watery or acid fluids, altered food, mucus, bile, vegetable growths, &c.; fæces of various kinds, with their admixtures; expectoration from the throat or respiratory organs; a flow of saliva; mucous or purulent discharges from various parts; albuminuria; calculi or mineral salts; particles of morbid products or formations; vegetable or animal growths or their ova, &c.

7. Local symptoms, or those having a local origin, are often due to some derangement of the *circulation*, or to the condition of the *blood*. In many cases of disease of the central organ of circulation, namely, the heart, the flow of blood is disturbed, in different ways in different conditions, and thus very obvious phenomena arise. The disorder may affect more directly the systemic circulation, either arterial, venous, or both; or the pulmonary circulation. The appearances produced by central venous obstruction, and the occurrence of dropsy in connection therewith, have already been alluded to under general symptoms, but they may also be of local distribution. Thus we may find dropsy confined to the

feet and ankles in cases of cardiac disease. Some impediment in the lungs may also assist in producing like symptoms. If any particular artery or vein is obstructed from any cause, similar localised phenomena, corresponding to its situation and distribution, will probably be observed. Certain *special* circulations have to be particularly borne in mind in this connection, the most striking being the portal. Any impediment affecting this circulation, whether within or outside the liver, is very likely to give rise to definite phenomena, such as ascites, &c., and these may be the chief or only signs of serious disease implicating the liver, or situated in its vicinity. Disorder of the renal circulation may also be mentioned here, although this is recognised by changes in the urine.

With regard to the blood, the best illustration of changes in this fluid, induced by some local cause, and giving rise to consequent local symptoms, is that connected with renal disease. These, at any rate, partly account for renal dropsy, which is often local; and they also originate other clinical phenomena.

8. There is a group of local symptoms which may be gathered under the term *mechanical* or *physical*. In the first place, certain passages or channels may be so encroached upon or narrowed, as to become more or less obstructed, and thus objects are directly prevented from passing along them. For instance, certain morbid conditions affecting the mouth or throat may impede the entrance of both alimentary substances and air, thus immediately interfering with swallowing and breathing. The nasal cavities, air-passages, or œsophagus may be affected in like manner. In internal parts, orifices, tubes, and canals are liable to similar conditions, and hence arise accumulations and other phenomena as local symptoms. Moreover, special allusion must be made here to the physical effects of neighbouring structures upon each other. They are liable to be mutually influenced directly by irritation or pressure in many diseased states. The symptoms thus originating are of course various, and they really belong to one or other of the groups already considered, but they demand particular recognition as a class. They are common to all organs and structures, but diseases of some of these are principally indicated by their mechanical effects on other organs or structures in their neighbourhood, for example, the pancreas. Under this head may also be mentioned the symptoms that occur in connection with rupture or perforation of certain organs and morbid conditions. It may further be observed that symptoms may themselves cause other secondary symptoms in a mechanical manner.

9. I think that it will be well to notice separately, that when certain organs are diseased, they are liable to originate symptoms in connection with other organs more or less remote, without any such obvious and direct relations between them as to account for the phenomena on physical grounds, or through the circulation. Such symptoms are induced through the medium of the nervous system, and they are of the nature of disordered functions. It is important that they should be recognised, not only because they may appear to point to disease of an organ which is not actually affected, but also because they are not uncommonly valuable as aiding the diagnosis of the real seat of mischief. For instance, vomiting, constipation, respiratory or circulatory disorder may be prominent symptoms of cerebral disease. There is, moreover, a reflex or sympathetic relation between certain organs, with which you should make yourselves acquainted.

I have now completed the general remarks which I intended to offer regarding symptoms, and I trust that these observations will have prepared you for their study in connection with particular organs and structures, upon which I propose next to enter. In conclusion, let me emphatically impress upon you the following facts with respect to symptoms:—It by no means follows that local symptoms are present even in serious diseases

of the parts upon which they depend; and still less is there any necessary relation between the gravity of the symptoms and of the complaint. Another point is that individual symptoms, both general and local, often require very thorough investigation as to details. And, finally, the study of the different ways in which symptoms are combined in different cases is often of great value, and ought always to receive careful attention.

A SHORT RETROSPECT OF THE SANITATION OF FORMER YEARS AS CONTRASTED WITH THAT OF THE PRESENT DAY. (a)

By FRANK J. DAVYS, B.A., F.R.C.S.L. &c.,
Coroner co. Dublin, Swords.

DURING my experience of 22 years as a Poor-law medical officer, and, on occasions when forcibly, both in public and private, advocating the adoption of hygienic measures, it surprised as well as pained me to have heard men who considered themselves well endowed with a more than ordinary amount of common sense and wisdom, argue that sanitation was but a modern theory, and was nothing more than an effort of some individuals to create a sensation, insisting that the death of the late lamented Prince Albert, to whose memory this Hall in which we are now assembled is dedicated, was the first impetus the movement received in this country, as it was alleged that Prince Albert's death was due to typhoid fever owing to improper sanitary arrangements. In vain could those wise men be persuaded that hygiene was not a modern philanthropic adoption, till reminded by me that so far back as 1552 Shakespeare's father was fined in that year for depositing filth in the public street as being contrary to the bye-laws of the Manor, and in six years afterwards he was assigned again for another breach of the sanitary laws. In fact, so far back as 1338 a sanitary law had been passed to prevent the pollution of rivers. Sanitary science, in fact, dates from very early periods, and formed an element in the well-being of every nation. We hear of it in the Mosaic code of the Jewish race, and to its rules and regulations in that code and the strict observance thereof may perhaps be attributed the great longevity of the Jews, and their escaping the dreadful disasters of epidemics which visited other people and nations with such fatal results. If we look back to the histories of Greece and Rome we have there also ample proofs that neither with the Grecians nor Romans was sanitation totally disregarded. The sanitary code of Lycurgus was remarkable for its strictness. The Greeks devoted much attention to their person, the cleanly condition and care thereof, and the manifestations of their genius and learning appeared to have progressed *pari passu*. 'Tis true that, notwithstanding their great learning in this respect, they appeared to have been ignorant, or perhaps pretended ignorance thereof, of the causes of diseases or epidemics; they treated such as we would term them, visitations of Providence, and definitely pronounced them to be punishments sent by some offended Deities. Though the Romans cannot be said to be great sanitarians, yet, this must be conceded, they considered that good water in Rome was as necessary a boon to the health of the people as the late Sir John Gray deemed the Vartry to be necessary for the health and happiness of the citizens of Dublin. The great aqueducts of Rome and the celebrated *cloaca maxima* are works that will remain as proofs of great sanitary engineering as long as the history of Rome shall be read. By the great aqueduct water was conveyed into Rome from distances varying from 20 to 30 miles.

Whilst I have thus shown that sanitation in some form or other was not unknown to the ancients, I must admit our forefathers suffered immensely by series of plagues and epidemics, whilst there seemed to exist a total disre-

gard of any sanitary precautions. After a long lapse of years, during which it might be said that nothing practicable in the form of hygienic measures was done, the progress of civilisation, with which I unite as its part and parcel, education, gradually opened the eyes of some deep thinkers to consider the causes of epidemics and diseases that decimated so many human beings, and here I will say at this period, at the close of the 18th century, we find the names of Cook, Howard, and Dr. Jenner. The name of Captain Cook was, as we learn in the account of his voyages, rendered famous as a sanitarian by his success in the suppression of scurvy, and to him is due the fact that lime-juice was always afterwards included as a necessary item in the commissariat of seafaring vessels. Howard as a sanitarian was remarkable for his discovery of the causes of the celebrated jail fevers, which he proved to have been due to over-crowding and other neglects in sanitation. But the great prevention to death and disease from that scourge—small-pox—was the celebrated discovery of vaccination by Dr. Jenner at the close of the 18th century—in 1796—a discovery which deservedly immortalises him, as there is not a doubt that vaccination was the factor by which countless numbers of human beings had been, and are being, saved from a loathsome illness and from death.

In about the year 1720 a distinguished lady, Lady Mary Wortley Montagu considered herself as the greatest benefactress and sanitarian when, at her suggestion, the inoculation of small-pox was introduced; no doubt this system continued to be largely adopted, and many of its advocates insisted that several would have died had they not been inoculated. I need not here observe that that pernicious practice has long since been abandoned, and that the inoculator, if discovered, is severely punishable by law. The immediate value of vaccination as a preventive to small-pox was not long unproven. It was shown by guaranteed returns that the mortality from small-pox was 88 per 1,000 deaths during the last ten years of the 18th century. It, however, decreased from 64 to 11 per 1,000 deaths during the first 60 years of the present century. It is 41 years ago since the first rules or laws of vaccination appeared, it is 28 years ago since vaccination was provided gratis, and it is only 14 years since it was rendered compulsory amongst children. There is not, I am sure, a Poor-law medical officer in Ireland who could fail to give the strongest evidence of its potency as a preventive of small-pox. I could, if this were just now the suitable occasion, offer substantial and undeniable proofs of the value of vaccination as a protective agent against small-pox. Yet, notwithstanding all these convincing arguments in favour of vaccination, there are hundreds, nay, and persons of education who are opposed to vaccination, and object to have their children in that way operated on.

It cannot then be a matter of surprise, though vigilant the public health officer may be, if small-pox now and then breaks out and does its work of destruction. I am confident if the Vaccination Act was further amended, so as to render re-vaccination every eight years compulsory, those who had escaped vaccination in their infancy would then be secured, and that the re-vaccinating system was thoroughly carried out, small-pox would be totally stamped out. Public notice was not rightly directed to the state of things in England, till the Returns of the Registrar-General and the Reports of Dr. Farr appeared as public documents. After some time the people, or, at least, those of position and influence, directed the attention of the Government to the facts disclosed in the First Report under the Health of Towns' Commission Act. This was in 1844. The sanitary condition of the country was, at this time, in a wretched state. Countless *nidi* of disease were apparent in every direction. Yet so apathetic and so obstinate were the people as a body that they opposed such measures as opening up of sewers or any other sanitary improvement. The Parliament, of that time, recollecting how the country suffered by the cholera of 1831, passed a Public Health Act in 1848. This Act empowered a formal inquiry to be held by direction of the Board of Health constituted by it, in any town where the death-rate

(a) Read before the Association of Medical Officers of Health in Royal College of Surgeons, Ireland.

was pronounced excessive. This piece of legislation like others was only permissive, and as much benefit as might be expected did not result from it. Yet I might say it was the first proof given by Parliament that the health of the people was of important consideration. Corporate towns, in many instances, took advantage of its powers to borrow money for sanitary purposes. The badly arranged and stupidly organised commissariat in the Crimean war led to serious illness and loss of life in our army. So many as ten thousand of our troops died in the winter of 1854 in the Crimea. Public feeling very naturally, both in England and Ireland was excited to the highest degree by such a disaster, and by causes which were alleged to have been preventible. The Government of the day having had their attention in a very forcible and public manner in the House of Commons directed to this loss in our army, it was at once decided to send out a Pathological Commission to inquire into the nature and cause of disease that cut away so many of our brave soldiers. At this juncture, Dr. R. D. Lyons, who was then as distinguished a pathologist and microscopist as he is to-day eminent as one of our leading physicians, was selected as pathologist in chief, and with him, Dr. Aitken, now of Netley, and the late Dr. Doyle, of Dublin, to proceed to the Crimea. I believe I am correct in saying these three pathologists were specially recommended to the Government by Sir Jas. Clarke, and Dr. Parkes, of London, as eminent and energetic men, and specially qualified for that important mission, on which they proceeded early in 1855. The result of their inquiries forms an able report, interesting for perusal. It was presented to both Houses of Parliament, and was considered of such merit that it was ordered to be sent to all stations of the British army at home and abroad. At this time also it was deemed necessary to establish at Smyrna a civil surgical hospital, and whilst I feel happy in having alluded to the services that one of our distinguished Dublin physicians, Dr. Lyons, rendered to our profession and his country as pathologist in chief in the Crimea, I also feel proud to say that one of the most indefatigable and able surgeons in connection with the civil surgical hospital in Smyrna was Dr. Robert McDonnell, of Dublin, whose prominent desire appeared to be to minister to the sufferings of the wounded soldier, and assist the nation at large. In fulfilment of these wishes he volunteered and did serve with great brilliancy in the heat of the war in the Crimea just before and after the fall of Sebastopol. In 1858 the Privy Council, by Act of Parliament, assumed the functions of the General Board of Health, and, at this time, hopes for sanitary reform became manifest. Mr. Simon was medical officer. The causes of disease were thoroughly inquired into, the results of these investigations appeared in published reports, which are not uninteresting for perusal.

It was in 1848 when fever took away hundreds of poor people, and when in its worst form typhus raged in hospitals and villages, and towns in England and Ireland, that Sir William Jenner and a few of his hospital colleagues determined that the numerous cases of alleged typhus were not quite alike in their symptoms, and that typhoid, or enteric fever, was caught by different, and yet preventible causes from that of typhus (and as subsequent investigations have proven), could, by proper sanitary precautions, be almost erased from the category of fevers. The mode by which sanitary schemes were carried out for the prevention of typhus fever, were so faulty, that in many instances the fever instead of being reduced in its number of cases, was quite the contrary; this was altogether due to bad sanitary engineering, sewer gases entering houses from the mode in which the sewers were constructed. It was well shown in the report by Dr. Buchanan, the Inspector who was deputed to inquire into this very subject, that in every town where the sewerage was properly carried out, there was an immunity from typhoid fever.

Time would not permit me to refer to inquiries, or the reports thereof, in reference to food adulteration, polluted water supply, and the various statements sent to those

in whom was vested the authority to inquire into such. I might say not till the appearance of the Sanitary Act of 1866 did the medical officer in rural districts in Ireland feel himself legally, in a sanitary sense, in a position to cope with the many fruitful sources of disease that presented themselves to him on every other occasion in the discharge of his professional duties. Now, having up to this, taken, I might say, a bird's eye view of the state of sanitary science from the times of ancient Greece and Rome, and having shown that hygienic measures were not despised by the Ancients, and that I have thereby refuted the argument that sanitation was only a modern idea; at the same time I have in a cursory manner shown that sanitary laws were only very slowly, and gradually introduced into England, and not till many lives were lost by imperfect sanitation. I approach the period at which I can speak from experience, as a public health officer in a rural district, showing very briefly what appears to me as beneficial results of sanitation; and what are still required to check disease, and to improve the condition of the people, morally, socially, and physically. I have just said that not till the Sanitary Act of 1866 appeared, did the now termed public health officer feel in a lego-sanitary position able to cope with the unhygienic state of the country, he felt armed with means to suppress, and abate nuisances as well as eradicate in numerous cases general sources of disease. During the three years previous, that is, from 1863 to 1866, there could not have been in any town or hamlet in Ireland, of a population of some thirteen or fourteen hundred persons, in which there existed a more thorough disregard of the commonest laws of sanitation than that of Swords, this was principally due to its being over crowded in the harvest and haymaking seasons, when from three to four hundred harvest men from Leitrim, Longford, Cavan, and Sligo, assembled in the town. The lodging-houses were then actually crammed with human beings. An idea of the over-crowding may be formed from the following:—On the night of 12th August, 1863, at 12 o'clock, I was called to see a harvest man who had been seized with illness in one of the lodging-houses. On arriving at the house, I was ushered into a small room in which there were three beds. I did not reckon the number of human beings in each, except in the bed in which my patient lay, and that contained three at one end (one of them was the invalid), and two at the other. Having prescribed for the patient, and commented upon the unsuitable—a mild word—position of the invalid, one of them jocularly said, "Just look up on the left sir, and see how the boys there are." On the left referred to, and to which there was no window or access beyond a "step ladder," there were stretched on the floor, with some thinly scattered straw beneath them, about forty men, who presented a most ludicrous appearance, each of them was encircled in a common sack or bag, the head alone appeared to me as the only uncovered part of the body. On visiting the house next day, I found that the small back yard was one mass of filth mingled with vegetable decomposing matter. In fact, during these three years preceding 1866, when visiting such persons at the cottages of the poor, I had often, before attempting to reach the bed where the patient lay, deemed it prudent to inquire from some member of the household if the jennet (generally a treacherous animal) kicked, the jennet occupying as he did a comfortable position, one frequently intervening between the patient's bed and the cabin door; but the warmest corner was always assigned to the pig, in a nook beside the common fire-hearth—the greater the heat and general comfort in that way the pig enjoyed, the family felt that the less food it would require. Each member of the household was expected to devote particular attention to the pig, and on no occasion did the family partake of a meal without some part thereof being given to the occupant of the comfortable corner. In addition to his ordinary meal, the poor man's wife was by her husband always enjoined to devote special care to the grunter in

his absence, and the poor woman impressed on even the youngest child to be kind to the pig, and what wouldn't she buy for them all on the day of its sale.

(To be continued).

Clinical Records.

ACQUIRED PHYMOSIS.

Under the care of RICHARD RYAN, M.D.
Medical Officer, Bailieboro Union Hospitals.

The following cases of the above mentioned affection possess some points of interest which induces me to place them on record:—

CASE I.—In the beginning of 1877, A. B., *æt.* 56, consulted me for what he called "gravel." The symptoms were difficulty in passing water, particularly towards the end of the act of micturition, when it came slowly in drops, and frequent desire to micturate. He had been so troubled for three years. I diagnosed an enlarged prostate, which a rectal examination seemed to confirm. I treated him for this for four months without any benefit; he had been treated by another medical man for a month previously, and with similar results. One day I was feeling the penis, and on trying to uncover the glans, I found that the preputial orifice would only admit a probe. Until I tried to retract the prepuce, I had no suspicion that there was anything wrong, as it hung quite lax beyond the glans. Having now found the real cause of the "gravel," I got the man to remain in town under my care, I slit the prepuce on a director along the dorsum of the glans, drew it back over the glans, brought the mucous and cutaneous edges together with fine wire sutures, and applied water dressing. The case did well, and he has not suffered from gravel since. He was the father of several children, but the youngest was four years of age at the time of operation, he had a child born to him within a year after. I think this is more than a coincidence.

CASE II.—In May, 1880, I was called to attend C. D., a married man, *æt.* 59, for "gravel." He had been subject to difficulty in micturition for two years. I found him suffering from complete retention for fourteen hours. On exposing himself for examination I observed a tense firm tumour in the region of the glans, which, from the feel, I judged to contain fluid. Attempting to retract the prepuce, I found the preputial orifice closed. I then tried to introduce a fine probe and succeeded; at the same time a jet of water escaped beside the probe, squirting half-way across the room, and the tumour collapsed. Some small flakes of white secretion also escaped. The urine passed amounted to a quart. I explained the nature of the case to him, and he came into town under my care. I operated as in the last case, and with a similar result. He has not been troubled with the "gravel" since.

CASE III.—E. F., *æt.* 58, a married man, consulted me in January, 1881, for a feeling of soreness in the prepuce and glans which much annoyed him in walking or sitting. The glans had not been completely exposed for three months. The prepuce could only be so far retracted now as to expose a circle of the glans about two lines in diameter. The parts were itchy and inflamed, causing him much irritation and loss of rest at night. The urine was high coloured, and deposited a reddish sediment. He was of a full habit of body. Having put him on suitable diet and medical treatment, I made a little pencil of lint which I smeared with citrine ointment and introduced as far as possible through the prepuce, this was renewed by himself after each act of micturition. By continuing this treatment for ten weeks, and increasing the size of the lint dilator, he was finally able to completely expose the glans, and he suffered no further annoyance since.

I may remark that I have never met a case of congenital phymosis. The people of this part of the country use the term "gravel" for almost every disease of the genito-urinary tract, including such different conditions as gonorrhoea, stricture, enlarged prostate, retention, hæmaturia, phymosis, &c., and it requires some tact to get at the particular symptoms from which they suffer. Having oracularly informed the doctor that they have "gravel," they have rather a poor opinion of him if he does not know at once which of these they labour under without expressing any opinion regarding the frequency of a degree of phymosis sufficient to impede or prevent the act of micturition, as in the first two cases, I now think it prudent to look out for it when making the local examination.

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

A CASE OF HEMI-GLOSSITIS.—A very rare affection occurred in the hospital service of Professor Ball. One of the nurses, a girl, aged twenty-three, of a strumous constitution, was attacked in the month of March, 1880, for the first time, with inflammation of the tongue, limited to the right side. After feeling a general *malaise* for four or five days, she was attacked in the night, with acute pain in the right half of the tongue, extending to the ear of the same side, and the next day the tongue was found to be considerably swollen on the affected side; and deglutition was impossible. After a fortnight all pain subsided, but the swelling did not entirely disappear. In August last, the same symptoms, but in an aggravated form, returned suddenly, the tongue was greatly tumefied, the pain excessive, and the fever intense. Speech was almost impossible, and it was not without great difficulty that the mouth was opened. On examination, the right side was coated, and filled the greater part of the mouth. An emetic was given, and sinapisms applied to the neck. The next day the pain increased in intensity, extending to the right ear; the free margin of the right side of the tongue presented the impression of the teeth. Pressure upon the inflamed organ was painful, the fever increased, and the salivation was abundant. Washes of decoction of poppy heads were ordered. On the fourth day the salivation was less abundant, and the organ diminished in volume, and it was easy to perceive that the swelling was arrested by the *raphé*. On the sixth day the symptoms again became intense, and injection of morphine was ordered, to allay the pain; a mixture was given with tincture of gelseminum and an enema of chloral. The following day the position of the patient was in no way modified; four leeches were applied to the sub-maxillary region, which produced a rapid amelioration, as far as the pain was concerned, and gradually all the symptoms abated, so that, at the end of three weeks, the patient was able to go on duty. Nevertheless, the swelling had not completely disappeared; there was never any trace of suppuration.

ENUCLEATION OF INTRA-UTERINE FIBROMA.—Before the Société de Chirurgie, a member read a pamphlet entitled "Contribution to the Practice of Enucleating Intra-Uterine Fibroma." In this work M. Dezanneau distinguishes pediculated uterine polypi from sessile fibromas. Ablation in the former is generally attended with little or no difficulty, whereas that of the latter often presents serious dangers for the patient. A woman of fifty-two years of age, having had four children, suffered for several years from loss of blood, accompanied with pain. She had also a fetid sero-sanguinous discharge. Her health was greatly compromised. On examination a voluminous fibroma was discovered, of which the lower part extended beyond the neck of the uterus for about an inch. M. Dezanneau practised ablation in the following manner:—Seizing the tumour with a pair of strong forceps, he brought it to the vulva; the uterus was felt to follow the movement, and come down with the tumour; this done, the forceps was placed higher up on the growth, and with the finger all adherence with the internal wall was broken down. The chain of an *écraseur* was placed above the forceps, and thus all was detached with facility, for the polypus being fixed near its root, torsion was enabled to be practised with the greatest ease. The patient lost but three ounces of blood. The uterus rapidly returned to its normal position and size under the influence of quinine and ergot. The author cited other observations, and all tended to convince him in the fact that sessile tumours can always be removed with comparative facility by torsion and the *écraseur*. M. Guéniot, commenting on the communication of M. Dezanneau, observed that he agreed with him in considering torsion to be the best means employed for detaching the adherences of interstitial fibrous tumours. As to pediculated polypi, traction is not without danger, because it could produce inversion of the uterus. There are cases in which it is extremely difficult to distinguish between a polypus and an inverted uterus, or to know where the polypus ceases and the mucous membrane of the uterus commences. M. Tillaux has given a good means of distinguishing between the two, that of pinching, or puncturing the part. If it concerned the morbid tissue, the operation would not be felt, whereas the same operation on the mucous membrane of the uterus

would immediately be perceived by the patient. M. Gillette considered that torsion was applicable to some cases of polypi furnished with pedicles. M. Desprès could not understand how a polypus could be confounded with inversion of the uterus. Vaginal examination combined with abdominal palpation was always sufficient to clear up a doubtful case. M. Gaéniot persisted in considering that in exceptional cases distinction between an inverted uterus and a polypus is sometimes impossible. M. Trélat could not believe that any special method was applicable to the ablation of intra-uterine polypi. The surgical indications are very variable, according to the cases. It was true that there are cases where the diagnosis is exceptionally difficult, but in the generality of cases, each time that it is possible to introduce the hysterometer five or six centimetres, one can be assured that the tumour does not consist of an inverted uterus.

TREATMENT OF PURULENT OPTHALMIA IN INFANTS.—M. Galezowski recommends touching, morning and evening, the surface of the conjunctiva with a brush dipped in the following solution:—Nitrate of silver, 5 grains; distilled water, 3 drachms. Immediately after, a second brush dipped in a solution of chloride of sodium should be passed over the same surface. By this second manœuvre the excess of the caustic is neutralised. Such is the treatment to be employed, says M. Galezowski; it is not necessary to be preoccupied with the abundance of the suppuration, the intensity of the chemosis, or the more or less bad state of the cornea.

FOR INTESTINAL WORMS Dr. Baylet prescribes a packet each morning fasting, of one of the following preparations, in a teaspoonful of honey or some other vehicle:—

For a child of less than three years—

Santonine	2 grains,
Calomel	5 "

in eight packets.

For a child from three to twelve years—

Santonine	4 grains,
Calomel	8 "

in eight packets.

For an adult—

Santonine	8 grains,
Calomel	2 "
Powdered gum	4 "

in eight packets.

AN EXTRAORDINARY CASE OF MANIA attacking a who's family of six persons, living in a village in the department of the Mayenne.—The father is sixty-four years of age, and the mother about the same; of the two sons one is thirty, and the other twenty-seven; two daughters are twenty-four and twenty-seven respectively. These six persons were attacked with the same kind of mania. They believe they are poisoned by some sorcerers, and imagine that the devil is in their clothes. They see his Satanic Majesty everywhere. At night they run about with little or no covering, and carrying innumerable images of saints and other religious relics about them in order to ward off the evil spirits. One of the daughters believes herself damned. Unfortunately the mania has rendered these poor people dangerous, for they attacked with stones all those they encountered, and the authorities have had to send them all to the asylum. The incident has not unnaturally excited great commotion in that part of the country.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, JANUARY 27TH.

The President, JOSEPH LISTER, F.R.S., in the Chair.

Mr. W. HENRY KESTEVEN ON

CASE OF XANTHOPSIS, OR PERVERTED COLOUR VISION.

H. L. C., a young woman, *æt.* 23, married. On July 15th, an exceptionally hot day, she exposed herself to the full heat of the sun, and was seized with acute pain in the occiput, and found that she saw all things red and green. As the pain passed off in the course of a day or two, this intense colouration diminished; ophthalmoscopic examination revealed the existence of a large patch of double contoured nerve fibres at the upper part of the disc of the right eye.

This colour, first seen, was very prominent, and gave evidence of the existence therein of some neuritis. The left disc was normal. Examination of her colour vision showed that the left eye was normal, but that with the right eye (the one affected, as described above) she saw all things yellow. This condition continued for rather more than three months, and then gradually passed away. The author suggested that the condition might be explained by the violent impression made by the rays of the sun impinging directly upon the retina. The case was seen by Dr. Buzzard and Mr. John Couper, both of whom confirmed the ophthalmoscopic appearances described.

Mr. MARCUS BECK ON

A CASE OF NEPHRO-LITHOTOMY.

This case closely resembled in many respects that communicated to this Society by Mr. Morris, differing chiefly in the fact that the stone could not be felt after the kidney was exposed, and its presence was only recognised by puncturing the gland with a fine needle, as recommended both by Mr. Morris and Mr. Barker. The patient was a young man, *æt.* 19, who had suffered for twelve years from symptoms of renal calculus. One year before he applied at University College Hospital, his symptoms had suddenly increased in severity, after a profuse attack of hæmaturia. From that time he was practically unable to earn his living on account of the severe pain invariably brought on by any movement. He suffered from considerable frequency of micturition. He only passed blood recognisable to himself on three occasions. He applied to various hospitals and medical men without relief. He was admitted into University College Hospital on July 22nd, 1881. He was anxious to undergo any operation in the hopes of getting relief. Treatment by rest was tried for three weeks without the slightest benefit. During this time no blood was noticed in his urine, but it almost always contained a very small quantity of pus. His symptoms while in the hospital were those ordinarily observed in cases of renal calculus. Examination of the loin under chloroform showed the absence of any recognisable renal tumour. A distinct fulness, which was always clearly visible in the loin, seemed to be due to contraction of the muscles over the tender kidney and possibly to some hypertrophy. On August 11th, 1881, the operation of lithotomy was performed. The incision was slightly nearer the last rib and a little more oblique than the ordinary colotomy wound. The muscles were very thick for so feeble a subject. The kidney exposed without difficulty in its lower half. Manipulation failed to detect the presence of a stone. The kidney was then punctured with an ordinary darning needle held in a pair of torsion forceps, and the presence and situation of the stone were easily recognised. Following the direction indicated by the needle, a knife was passed into the kidney with its edge directed upwards. The bleeding, which was at first very alarming, was averted by the presence of a sponge in less than one minute. The wound was then dilated with a pair of polypus forceps, with which the stone could be felt, but not grasped. The finger was therefore inserted by the opening into the pelvis to guide the forceps, and the stone was then easily removed. The bleeding ceased at once. A large drainage tube was inserted with its deep end in the fat about the kidney, and the wound sutured. The whole operation was performed under the carbolic spray, and the wound was closed with carbolic gauze. The stone weighed 29 grains. It was heart shaped, and had apparently been moulded to the form of a calyx. It was composed chiefly of uric acid. The after-progress of the case was uninterruptedly favourable. The shock of the operation was not great, and lasted only for a few hours. There was considerable vomiting for the first 36 hours. He passed no water for 12 hours, and at the end of that time 12 ounces were drawn off by a catheter, after which he passed it naturally. No urine escaped from the wound till the 7th day. It then flowed abundantly till the 11th day, when it ceased to pass by the wound. At the end of the third week he sat up in bed, at the fourth week he left his bed, and at the end of the fifth week he went to a convalescent home with the wound soundly healed. The temperature never rose above 101.5°F., and even after the 11th day it remained below 100°F. He suffered no pain after the second day. This case presented all the conditions justifying the operation. The patient was totally incapacitated from earning his living. It might be presumed that the stone was too large to pass by the water, as it had ex-

isted in the kidney for a period of twelve years. Treatment by rest had been tried both in University College Hospital and elsewhere without benefit. With the exception of the few symptoms due to the stone, the patient was in "good health, and he was young, and not too fat. A small quantity of pus was almost constantly present in the urine, showing considerable irritation of the pelvis. One point in the case specially worthy of notice was the sudden alteration in the symptoms that took place about a year before the operation, accompanied by profuse hæmaturia. Up to that time jolting, such as is caused by riding in a train caused little pain, and there was no frequency of micturition. The attacks of pain were always brought on by prolonged walking. After that time there was gradually increasing frequency of micturition; a pain was caused both by jolting and walking. It seemed probable that this change was caused by the stone passing from the calyx into the pelvis of the kidney. The form of the stone showed that it was originally moulded in a calyx, and at the operation it was found in the pelvis. A similar difference of symptoms has been observed in other cases of renal calculus—in some the pain brought on more by the movements of the muscles in the neighbourhood of the kidney than by jolting of the body, and in others equally by both. Frequency of micturition is also a very variable condition. As all the graver consequences of renal calculus arise from the presence of a stone in the pelvis, and as the chances of cure by the stone becoming encapsulated are certainly greater when the calculus is lying in a calyx, it is important, if possible, to distinguish these two conditions. Future observation might show some such rule as the following to be true:—When the pain is induced by walking only, and there is no marked frequency of micturition, the stone is probably enclosed in a calyx; when the pain is greatly intensified by jolting of the body, as well as by walking, and when there is great frequency of micturition, the stone is probably lying loosely in the pelvis. With regard to the operation itself, the chief points of interest were the success of the proceeding of puncturing the kidney with a fine needle in finding a stone which could not be detected by manipulation, the rapidity with which the bleeding from the kidney was arrested by simple pressure with a sponge, and the simplicity and ease of the whole operation, which was, in fact, no more difficult than an ordinary perineal lithotomy. It showed, however, that, in order to avoid too great loss of blood, the knife should be used as little as possible, and the wound enlarged by tearing. The rapid healing of the wound was, no doubt, in a great measure due to the thickness of the kidney substance cut through, which prevented, to a great extent, the escape of urine by the wound. The importance of the antiseptic treatment in such cases could hardly be over-rated, when we consider the depth of the wound, the amount of decomposable matter which necessarily lies in it, and the dangers of septic pyelitis and disseminated suppuration of the kidney.

Mr. HENRY T. BUTLIN ON

A CASE OF RENAL LITHOTOMY.

The patient was a young man, æt. 20, who, for ten or twelve years had suffered from severe attacks of neuralgia of the testis. The attacks occurred very frequently, and lasted from thirty minutes to two or three hours. After his admission into St. Bartholomew's Hospital in September, Mr. Willett discovered that the pain was seated in the right side of the abdomen as well as in the testicle, and that the symptoms were those of renal colic rather than of neuralgia of the testis. The urine contained crystals of calcium oxalate, and occasionally a trace of albumen, but no blood or pus. In spite of the pain, the patient's health was fairly good. As treatment did not afford permanent relief, Mr. Butlin cut down on the kidney through a vertical incision in the lumbar region. The kidney appeared to be healthy, but a calculus was discovered and removed from the renal pelvis. It was composed of calcium oxalate, was about as large as a filbert, and quite prickly on the surface. The patient made a good recovery, so that two months after the operation—which was performed on Oct. 5th—he was discharged free from pain and quite well, except that a small quantity of pus was present in the urine. Lister's antiseptic dressing was at first employed, but this was abandoned two days after the operation, and the wound was treated, as far as possible, like an ordinary lithotomy wound. Urine ceased to flow through it after about the seventeenth

day. This case is of interest, not merely as a contribution to the successful treatment of renal calculus, but as an important contribution to its diagnosis. The absence of blood in the urine is especially remarkable when the situation and nature of the stone is considered.

Dr. WHIPHAM and Mr. J. W. HAWARD ON

TWO CASES OF NEPHROTOMY FOR THE REMOVAL OF RENAL CALCULUS.

CASE I.—A married woman, æt. 23, was admitted into St. George's Hospital, under Dr. Barclay, on September 10, 1880. The family history was good. The patient gave a clear history of having passed a calculus seven years previously. It was a rough stone, and gave much pain. After this she remained in fairly good health, and although she experienced no paroxysms of pain, yet she was never free from constant uneasiness in the left side. She had never been very robust. Nine weeks before she came under Dr. Barclay's care the pain in the left loin recurred with great severity. She lost much flesh, and the urine became "very thick" and offensive. She experienced pain on micturition. While under observation she complained of shooting pains in the left loin, weakness, and loss of appetite. The abdomen was flattened, and neither dulness nor swelling were detected on the right side. On the left side the muscles were firmly contracted, and therefore no tumour was found. There was great tenderness over the left hypochondriac and lumbar regions, and slightly so in the right groin. The urine contained much pus, and was alkaline. During her residence in hospital she suffered much pain in the region of the left kidney, and had occasional perspiration. Eventually the urine became acid, and the pain was much relieved, and she was discharged somewhat improved on October 23, 1880. On March 21, 1881, she was readmitted under Dr. Whipham's care, when she stated that she had in the interval never been free from pain, and that for the past week it had been intense. The urine had been persistently turbid, and she had vomited on March 20. She had noticed a few clots of blood in the urine. The abdominal tenderness was so great that no satisfactory examination could be made. As no improvement took place, Mr. Haward was called in consultation, and he decided to attempt to remove the calculus by nephrotomy. The patient having been placed under the influence of ether, a tumour was distinctly felt in the left loin, and an incision was made as if for lumbar colotomy. The surface of the tumour was exposed, a bistoury thrust into it, and the finger passed into the dilated pelvis of the kidney. A firmly fixed stone was at once detected, and without much difficulty removed, together with a few small fragments. Very little blood was lost. The patient did extremely well, and on July 16 was discharged, there being still a little discharge from the sinus in the loin, and a small quantity of pus in the urine. The stone weighed forty-seven grains, and was composed of phosphate of lime.

The second case was that of a woman, æt. 56, who was admitted under Dr. Whipham's care on October 3rd, 1881. She had suffered pain on micturition for several years. In 1879 both gravel and blood were present in the urine. She was not aware that she had passed a stone. In October, 1880, she had a sharp attack of vomiting, followed by pain in the left lumbar region and hæmaturia. While under observation she complained of an increase of this pain, and the belly was generally tender. There was great muscular resistance on the left side, and fulness and tenderness on pressure on the right side. Fluctuation was detected on October 6th in the left loin, and Mr. Haward, who saw the patient on that day, made an incision into the swelling. During the night a copious discharge of pus occurred, with great relief to the pain. No calculus could be found; the urine contained much pus. On November 3rd, the patient having become worse, the incision was extended, and the wound thoroughly explored. No calculus was found; but as the kidneys and tissues were so firmly matted together, no further operation was deemed advisable. The patient died next day. At the post-mortem examination it was found that the kidney lay in a cavity, whose contents were purulent; that its pelvis was dilated, and communicated with this cavity by a large irregular opening, through which one or two fingers could be passed. Two or three small fragments of stone were found in the calyces; a large branching calculus occupied the calyces of the right kidney. These two cases were brought forward as illustrating the propriety

of cutting into the kidney in cases where the diagnosis of renal calculus is clearly established, and as affording encouragement to the surgeon to perform the operation of nephrotomy in the earlier stages of the disease, rather than to postpone surgical interference until dilatation or suppuration of the organ has occurred.

Mr. CLEMENT LUCAS warmly congratulated the authors of the papers on the success attending their operations. He had not himself had the good fortune to remove a stone in such manner, but last year he had under treatment a male patient aged 49, who two years previously had suffered from painful hæmaturia. Treatment afforded relief, which persisted nine months, when pain recurred, and with it bloody urine also, and in May last these symptoms were much aggravated, so that the man became anæmic from loss of blood. He was kept under observation during one month, the blood clots discharged in the urine being frequently examined and found to be moulded on the shape of the pelvis of the kidney. In June an operation was performed: by a transverse incision the surface of the kidney was exposed, but no stone was discovered. It was to be regretted that puncture of the organ was not resorted to, for he (Mr. Lucas) now felt satisfied that this was always a justifiable and simple procedure under such circumstances. In his case the temperature never rose over 100 deg. Fahr., and the patient left the hospital, healed, on the 17th day after the operation, it being a curious fact in connection with it that permanent relief was experienced. At present the man was under Dr. Pye-Smith for phthisis only; and it might be assumed that he possessed a strumous rather than the calculous kidney which had been diagnosed in his case.

Mr. BARKER remarked that the recent progress of events had exposed the exaggerated opinions formerly entertained as to the danger of incising the kidney. Two years ago he recorded a case in which, through accident, a man was so severely injured that his loin was slashed through to a depth implicating the kidney to a serious extent, but notwithstanding the patient made a satisfactory recovery. Again, about one and a-half years since, he had freely cut into a diseased kidney with a bistoury in vain search to find a possible stone, the bleeding being of the most temporary description; and in yet another similar instance he experienced only slight bleeding of the kidney cortex on cutting into it, while such as did arise very quickly ceased. He felt that no fear need in future be entertained to prevent free exploration of the kidney by puncture. Mr. Barker concluded by declaring a preference for freely cutting into the kidney for removal of the stone, this seeming more advisable to him than attempting to reach it through the pelvis with the view of avoiding even extensive wounding of the organ.

Mr. M. BAKER said it should be remembered that cases of another kind than those described in the papers present themselves for treatment. He had related such a case at the late Congress. The patient was a woman, aged 43, with tumour in the right renal region. Pus was always present in the urine. The kidney was first punctured and pus drawn away, and three weeks later the tumour was explored through a lumbar incision, and found to consist of a sacculated kidney containing a large branched phosphatic calculus, which was dislodged with difficulty, there being profuse hæmorrhage. The patient was much collapsed afterwards, never rallied, and died three days after operation. The calculus weighed nearly two ounces. Such cases were distinctly different from the class under discussion, which were those of small calculi. In all cases of the nature he had described, he would advise removal of the kidney.

Mr. BARWELL had never removed a stone from the kidney, all the examples of renal calculus coming under his care having been such as necessitated extirpation of the entire organ. He thought the papers read suggested the importance of not permitting cases in which stone should be suspected, to go on in pain and misery, when simple incision and puncture would at once and certainly settle the nature of the mischief. The incision could be performed absolutely without danger, and might even be looked on as a trivial operation. It involved no serious risk of any kind to the patient. He suggested that the cases described should be kept under future observation, in order to ascertain whether any tendency had been induced in them, either to reformation of the calculus, or to loosening or floating of the kidney itself, as an after-effect of the operation.

Dr. BARLOW made reference to the dangers of operating on such cases as that related by Mr. Baker, but which were not fairly to be placed alongside of such as were fit subjects of Mr. Morris's operation, for comparison of the results obtained. Three years ago he (Dr. Barlow) had under his care a Polish Jewess, who for a long time had been passing pus with urine to the extent of one-third of the total amount. She was cachectic in appearance, and had a large renal tumour in the right loin. This was examined, patient being under ether, by Mr. Couper, and calculi were discovered by the grating produced by manipulation. Dr. Barlow had suggested puncturing the mass with a hypodermic needle, but this was not done. Next day an incision having been made down to the tumour, the pus was cleared out and three large calculi removed, but the kidney could not be extirpated in consequence of extensive adhesions. The patient died, but, being a Jewess, no post-mortem could be obtained. In another case of his own, a scrofulous kidney was operated on without any blood at all being lost from it.

Dr. LONGHURST considered the cases reported indicated the appropriateness of the operation, but still great discretion would be required in selecting those fittest for the purpose. Early life favoured success, but middle and late life endangered it. In his own experience, he came into relation with two cases last year. One of them, a nobleman, with renal calculus, was urged to submit to operation when attacked with pain in Paris. He refused, and later on, having returned to England, died, when post-mortem examination revealed that both his kidneys were blocked by calculi. In the other case, a gentleman had been for eighteen months troubled with symptoms of renal disease, and at the end of this time passed several small stones. Adjourning to Brighton, he rested quietly there for some time, and was much easier. Returning to town, he again passed a small stone, and had since enjoyed good health. He was between 60 and 70 years of age, and operation in his case would have been attended with danger, while being, as the result demonstrated, wholly unnecessary.

The PRESIDENT was sure that everyone would congratulate the surgeons who had recorded the cases under discussion, on the happy results they had obtained. In connection with them, however, there were one or two points of pathological interest that deserved to be noticed. The calculi had been shown not to be of uniform chemical composition, urates, oxalates, and phosphates having been found in different cases, and it could not fail to be of interest to know this might occur. It would also, in this connection, be an important gain could it be ascertained at what rate renal calculi increased in size, the difference between the rates of growth of renal and vesical stones being a very striking factor. The reason for it was difficult to explain. Might it be consequent on the greater concentration of the vesical urine as compared with that in the kidney? Mr. Butlin's case was most instructive from a diagnostic point of view, testicular pain alone having been the guide to renal mischief in it, the additional difficulty of no blood in the urine having been associated with it. Great importance also attached to the proof given of the value of an exploring needle as aiding the detection of stone in the kidney; it might be found, however, that an acupuncture needle fixed on a handle would form a more efficient instrument for the purpose than a needle held in a forceps. This simple instrument gave at once reliable information not only as to the presence, but even as to the size of the stone. Mr. Beck had shown the expediency of cutting down to the calculus through the organ itself, and the flow of blood momentarily encountered reminded him (Mr. Lister) of an occasion on which he cut into the liver in the presence of Sir J. Fayer, and being alarmed by the immediate gush of blood, was reassured by the latter surgeon's remark, that the occurrence was unimportant, and that the bleeding would speedily cease, which it did.

Mr. HAWARD was glad to hear and endorse the opinions expressed favourable to early operation. He agreed that total removal of the kidney was advisable under such circumstances as Mr. Baker narrated. In his own first case, however, evacuation of pus afforded relief. Removal of the kidney was less simple than removal of the stone, and in Dr. Whigham's case this plan of procedure was rendered impossible by the dense matting together of surrounding tissues.

ment should be addressed to the Publishers.**The Medical Press and Circular.**

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, FEBRUARY 1, 1882.

RENAL SURGERY.

AMONG recent achievements in the domain of operative surgery, none is likely to be fraught with greater benefits to humanity than the improvements effected in the modes of dealing with calculous deposits in the kidney. Not only are the symptoms produced through the presence of these bodies distressing in themselves to a degree that renders life a burden to the unhappy sufferer, but they necessarily tend to put a period to existence, which, moreover, is terminated amid sufferings that evoke most painful reflections in the mind of every sympathetic on-looker. It is, therefore, a matter for hearty congratulation that surgical skill has now so far triumphed over this particular form of disease as to be in a position, not merely to determine the presence and nature of the trouble, but, in a majority of cases, to successfully remove it also; and this at the expense of the least amount of risk compatible with the performance of an operation involving the exposure and mutilation of an abdominal viscus.

To Mr. Henry Morris must be ascribed the credit of reviving a procedure designed to effect this object; and especially must his name be associated with it in the future as that of the surgeon who led the way to its adoption as a modern improvement, by illustrating the certainty of success attending its performance in suitable cases.

The paper communicated in 1880 to the Clinical Society of London by Mr. Morris, and entitled Nephrolithotomy, is the starting point of the later history of the operation; and on Friday last there were added to this, three other contributions on the same subject,

accounts of which will be found in another column of our present issue. These reports, together with the discussion that ensued upon them, may be accepted as demonstration of the feasibility of removing renal calculi by operation; and in several ways they tend to show how far such operations may be legitimately resorted to with good prospects of successful results. Perhaps the most interesting communication was that made by Mr. Butlin, whose admirable description of the difficulties of diagnosis encountered in his case, calls for unstinted praise. The history he supplies should be accepted as a timely warning against hasty conclusions respecting the nature of a complaint; for it cannot be denied that, even now, it is far too common a practice, particularly with younger surgeons, to "jump at" diagnosis founded on the presence or absence of special indications usually associated with the presence of a suspected disease. In the instance referred to, the principal guide to a correct judgment was that afforded by acute pain in the testis; there was no bloody condition of the urine, no deposit, except a trace of calcium oxalate, no special lumbar pain to point out the real seat of mischief; and we may accept it as undoubted proof of diagnostic ability that the ultimate decision on the case was so perfectly accurate. Once finally settled that the kidney contains a stone, then the question of operation is virtually decided also: but the management of this stage of treatment is the most critical part of the whole matter. In Mr. Morris's case the presence of a stone was revealed by the resistance it offered to the point of the knife introduced into the kidney; it must be evident, however, that such an occurrence is possible in the most favourable circumstances only, viz., when the foreign body lies superficially in the kidney, and presents at some point in its surface accessible to inspection or to touch. Very different is it when, as in Mr. Beck's case, the calculus is deeply imbedded; then, if the knife alone is to be depended on for proof of its existence and determination of its location, there must be performed a series of exploratory incisions the magnitude of which might well deter from the attempt. All this, happily, is avoided by employing for such sounding purposes, an ordinary needle, preference having been expressed for a darning needle held in a torsion forceps. With this simple instrument punctures may be made in all directions in the kidney until the stone is discovered, and this without the least fear of creating either serious hæmorrhage, or subsequent irrecoverable injury of the tissue. A little enthusiasm respecting this brilliant suggestion may very properly be excused; young as the proceeding is at present the advantages it can already justly lay claim to entitle it to all the praise accorded it, while in the future it will probably be productive of practically unlimited blessings.

The position of the stone being known, and an idea of its size communicated by the exploring needle, the question of removal arises. To effect this, two methods are proposed. By one, attempts are made to reach it with as little injury as possible to the renal parenchyma; the other is to cut boldly down to the calculus, and extract it by the opening thus made. Almost universal assent is now accorded to the latter plan, the older objec-

tions on the score of bleeding being, by one accord, overruled. The evidence in favour of this proceeding is both interesting and conclusive. Several operators have described how at the first incision into the kidney substance, even alarming bleeding occurred; but all agree that this almost immediately ceases, and is succeeded by no hæmorrhage of any importance, while after-recovery of the cut structures is uninterrupted and complete. The testimony to this effect admits of no dispute, and without entering into any theoretical explanation of the fact, may be forthwith accepted as an unassailable truth.

So much for the removal of renal calculi by operation, which may now be safely regarded as among established surgical procedures. We need not pause to describe the methods adopted for reaching the kidney; they may be varied by individual surgeons in slight degree, but generally they will be such as are followed in lumbar colotomy. We must, however, advert to the question of selection of cases in which the operation may be pursued with advantage. Mr. Marrant Baker describes a case in which nothing short of entire removal of the kidney could have been attended with successful results. A moment's consideration of the facts surrounding it will prove this, and demonstrate also the inutility of any other proceeding wherever a similar state of things is found to exist. The kidney in these cases is little more than a pus-secreting sac, in which enormous calculi are developed to the extent of even filling the entire space. In Mr. Baker's patient the stone weighed nearly two ounces. Moreover, it rarely happens in such examples, unfortunately, that removal can be effected, owing to extensive adhesions set up round the kidney. Dr. Whigham's communication contains a description of the kind. Such cases are obviously not to be included among those in which nephrolithotomy is possible, and at once they should be eliminated from the discussion. Whether, however, as Dr. Longhurst suggests, it will be found that all persons of over middle age are to be considered unfavourable subjects for the operation, will, we imagine, depend on the connection found to exist between the condition of the kidney and the period during which it has been the seat of calculous deposit, and here is evident the wisdom of Professor Lister's suggestion, that inquiries should be instituted with the object of determining the rate of growth of renal calculi. We venture to think that the duration of existence of the stone in the kidney will, by and-by, be the principal factor employed in deciding on the propriety of operating for its removal, irrespective of age alone, other things, such as constitutional state, &c., being favourable. It will, however, be essential to the satisfactory progress of the operation that some definite knowledge shall be obtained respecting the relation between first symptoms of renal calculus and the growth of the calculus itself. Concerning this question, we are at present wholly in the dark; too much enlightenment in respect to it cannot be obtained. How far Mr. Lister's ingenious supposition that the differences observed between rate of growth of vesical and renal calculi is founded on truth remains to be shown; it is probably not far from a real explanation of the matter.

Thus, then, eliminating those obvious cases in which,

from various causes, the kidney has ceased to preserve its essential structure, and is thoroughly invaded and transformed, we may accept the certainty that a means is offered of restoring the functional equilibrium of patients suffering from calculous disease of the organ, and that so far the operation can be safely performed in young subjects who have not passed the stage of disease at which general disintegration of the tissue of the organ supervenes. This is itself a triumph of surgical art, and to its authors is due, and will be accorded, full measure of the praise they so richly deserve.

THE DUBLIN HOSPITALS BOARD.

A DUBLIN morning paper recently made the following remark respecting the efficiency of the Board:—

“It may be argued, and of course with some truth, that the entire Board of Superintendence is a sham, and that, therefore, to put this gentleman (Sir George Owens) upon it would be quite appropriate. Such an argument we could not gainsay. The Board as at present constituted is a sham, and mainly for the reason that on it are a number of men connected with the administration of the Dublin Hospital. The entire system of the management of the Dublin Hospitals requires overhauling, and to expect this to be done by the managers themselves is very Utopian indeed. If the Board of Superintendence were composed of ‘live men’—to use a Yankee expression—they could do public service, but constituted as the Board is, it is worse than useless.”

The Dublin Hospitals Board was established by the 19th and 20th Vict., cap. 110, in the year 1856, for the purpose of superintending the distribution of £17,000 granted each year by Parliament towards maintenance of Dublin hospitals, and, as a vigilance committee, to watch the management of these institutions. But, in fact, the supervision is of very little value, because the Board has heretofore been packed with members of the management of the subsidised hospitals, who are thus engaged in supervising themselves, and naturally find no fault with their own administration. Moreover, the public gains little or nothing from the proceedings of the Board, and is debarred from criticising either its acts or the management of the hospitals under its charge by the fact that the Parliamentary Report of its doings is habitually kept back until the time for effectual criticism has passed away.

For example, the latest information which the public or Parliament now possess of the proceedings of the Board is contained in the Report for 1881 which lies before us. This document was laid before Parliament twelve months ago, and was then nearly four months old, for it bears date November 2, 1880. But the facts and figures contained in it are six months older still, for they refer to the year ending March, 1880, and some of the transactions reported upon occurred a year earlier than this, in April, 1879.

Thus any one who desires to learn or to criticise the management of the subsidised hospitals is limited, in doing so, to transactions of three years ago, the interest in which has long passed away. We want to know—

a. Is it absolutely necessary that the year reported on should end in March instead of September?

b. Is it not possible to produce the Report of what occurred in March at an earlier date than November?

c. Is it necessary that the document should, after its completion and adoption by the Board, be kept secret from November to the following March?

As to the contents of the Report, we would say that the secretary seems disposed to tell as much of the real truth as the Board will allow him, but it could not be reasonably expected that his criticism would be very trenchant, considering that his paragraphs have to be revised by the persons criticised. As an instance of this, we note that in no issue of the Report has comment been made upon the monstrous expenditure of some of the subsidised hospitals. No notice is taken of the fact that in one hospital to which the public money goes, every bed maintained costs just £90 a year, and that of this monstrous sum the successive sick occupants consume only £25, while the voracious establishment of officials swallow up the remaining £64. In other words, it costs the public in that hospital about £2 10s. for officers to spend £1 on the sick patient.

Is not this a subject worthy of consideration by the Dublin Hospitals Board, and why has it not been long since dealt with by them? We shall be glad to hear of any possible excuse.

THE SUNDERLAND CONSPIRACY CASE.

On the clearest possible evidence, and to the perfect satisfaction of judge and jury, and to a crowd of interested townspeople assembled in the Court, Dr. Abrath has been acquitted of the foul charge brought against him; he has also received the assurance of an intelligent jury "that he left the Court without a stain upon his character." The result of the verdict is to throw upon some persons in the employ of the North-Eastern Railway Company the grave responsibility of preferring and prosecuting to the bitter end a grave and base charge of a very malicious and disgraceful character. Nothing could have been fairer and more straightforward than the conduct of Dr. Abrath and McMann from the beginning to the end of these proceedings; everything was done to bring the Railway Company to reason in a matter of so serious a nature. Mr. Day, counsel for the defendants, in a speech of remarkable force and ability, put this in the clearest light. Nothing, said he, could be freer from suspicion, for McMann's solicitor entered into a correspondence with the Company's solicitor as early as November, 1880, when he proposed that the Company should make the fullest investigation, and by its own officers; and after having become satisfied of the *bonâ fides* of the case, a certain moderate sum of money should be paid over to him for his client, to abide the issue, at the end of two years, so as to give ample time and opportunity to the Company to test in every way the duration and extent of the injury inflicted. This very reasonable offer was, after a lengthy correspondence, refused, the Company electing to harass Dr. Abrath and his patient, sending detectives to look after them, and who, it was said, were encouraged to make libellous statements against them, and spread about reports which were likely to blast the reputation of the doctor. Little progress, however, appears to have been

made in this way; and when, at the end of nine months, the case came on for trial at Newcastle (July, 1881), the Company, acting under the advice of counsel, preferred to settle the case out of court, rather than risk the verdict of a jury. A sum of seven hundred and twenty-five pounds was paid over to the injured man, and a further sum for law costs. In a week or two from this time a new difficulty presented itself. McMann was cursed with a superfluity of worthless friends, who hovered around his sick bed; and so long as they could get money out of him, or saw a chance of sharing in the money obtained from the Railway Company, they were satisfied to remain friendly; but when they discovered they were to be balked of their prey, that Dr. Abrath and other friends had taken steps to place the money out of their reach, where it could not be got at and squandered in drunkenness by them, they then sought to obtain it by violence, and went so far as to threaten Dr. Abrath's life, until, at length, he was obliged to appeal to the law for protection. Finding themselves foiled in this direction, they put themselves into communication with the medico-legal officers of the Railway Company. In the course of a very short time, and out of the flimsiest materials, a case was trumped up, which last week happily ended in the signal discomfiture of every one engaged in the prosecution. That the judge should have felt it necessary to seriously animadvert upon the character of such witnesses, or that the jury, after five minutes' deliberation, should have expressed their disgust, could have surprised no one who had mastered the facts of the case.

As to the medical evidence tendered on the part of the prosecution, this, we gather from the reports published, was not free from that partisanship which often does damage to the best cause. What indeed, could be expected of men placed in the invidious position of having to blow hot and blow cold? In July last they were clearly of opinion that McMann had sustained an injury of the spine of some sort. Mr. Wheelhouse, of Leeds, was satisfied of this, but would not pledge himself as to its extent, and therefore he requested the Railway Company to permit him to make another examination; but this his clients would not accede to, and the case, as we have said, was settled with or without the concurrence of the doctors. At Durham, last week, it was thought better not even to put two of them into the witness-box; their duties apparently being to assist the learned counsel in throwing mud at the medical witnesses for the defence; and to such an unusual extent was this carried that at last the judge angrily interposed, exclaiming, "This is really too bad." Again, in his summing-up he remarked that "he hoped that the person who was acting as prompter was ashamed of himself;" but nothing less than an expression of public opinion, backed by the judge will raise a blush on the cheek of those whose highest ambition is to earn a fee at the expense of others' reputation. In short, the bitterness with which this case has been fought out is not a little remarkable, as it gives colour to a suggestion thrown out, that it was done with the intention of intimidating the profession—"letting the doctors see that Railway Companies could, if they chose, wield an instrument of torture in cases where too humane a view was taken of an injured patient."

The general bearings of the case were ably summed up

in the *Times* newspaper last Friday; the editor says: "As for the North-Eastern Railway Company, they are probably sorry by this time that they did not take the obvious course of weighing the character of witnesses against the huge improbability that a medical man occupying a good position would stake everything upon the chance of successfully conspiring along with a man of McMann's class to secure a relatively paltry prize. They must be held to have displayed most culpable levity in bringing so grave a charge upon grounds so utterly inadequate, and the public will probably be disposed to think that mere loss of the case is by no means a sufficient punishment. No doubt railway companies are obliged to be on their guard against imposition, but they do themselves much injury by engendering the suspicion that they are disposed to use the power of the purse, and the great advantage which law and circumstances alike award to corporations in order to crush inconvenient claimants." The mean and ignoble tactics resorted to have only had the effect of leaving the Company to repent at leisure of having prosecuted a false and malicious charge against a medical man to whom professional honour should be as dear as life itself.

Notes on Current Topics.

The Expurgation of the Medical Register.

We spoke recently of what the Medical Council might and should have done, in discharge of the duty imposed upon it by the Medical Act, in removing from the Register the names of Levenston and Jamson, the one for obscene quackery, the other for making use of false titles and qualifications. We observed that the Medical Council had, in the case of Jamson, simply passed on their own duty to the College which licensed him, and cast the responsibility off their own shoulders on to those of the Edinburgh Colleges. We are informed that the exercise of the power of erasure by the Council was, in the case of Levenston, attended with great trouble and expense, and that there are great practical difficulties in the way of the employment of the authority which the Council possesses for this purpose; but we have a difficulty in understanding how this can be. We believe that it was under the 14th section (that which enables the Registrar to strike out the name of a person who is believed to be dead or gone away) that these expensive proceedings were taken; but it is of the authority given by the 29th section (to remove the name of a person guilty of infamous conduct in a professional respect) that we have spoken and our complaint is that, instead of availing itself of this law, the Council has simply reported the delinquency to the licensing body concerned, and left the name on the Register pending the action of that body. The section says that the name of any person may be removed if "after due inquiry *he shall be judged by the Council to have been . . . guilty of infamous conduct in any professional respect,*" and it seems to us that these words make the Council the sole judges of the matter and preclude any appeal whatever or any reversal of the decision arrived at, and therefore, preclude any heavy expense in the exercise of the power

which the section confer. If we are right in our reading of the law the Council must institute "due inquiry," but, having done so, may expel the offending practitioner from the profession by its own mere motion, and we, therefore, complain that the Council has placidly allowed the names of quacks and forgers to defile the official list of the profession, and has left the licensing bodies to do the work given to itself to perform.

New Lunacy Law for Ireland.

UNDER the County Court Jurisdiction in Lunacy Act of 1880 (43 and 44 Vict. cap. 39) a new system has been established for the certifying and committal of lunatics in Ireland, and a series of rules for the execution of the new law have been thereupon issued by the Judges of County Courts. Small cases in lunacy may henceforth be heard by civil bill in the County Courts, and the affidavit of medical practitioners who have examined the lunatic will be required. By the new rules "the medical affidavit shall set forth, distinctly and particularly, the character of the alleged lunacy, and the evidence as to demeanour, conversation, acts, and physical causes, upon which the opinion of the medical deponent as to the soundness or unsoundness of mind of the supposed lunatic shall be founded." Thereupon the Judge may, if the case be uncontested, make an order for the custody of the lunatic, and the guardianship of his or her property. If the case be disputed the Judge "may direct any qualified medical practitioner, other than the practitioner upon whose affidavit the civil bill has been grounded, to visit the supposed lunatic and to report confidentially to the Judge upon the circumstances of the case. The qualified medical practitioner so visiting and reporting under the direction of the judge, shall be allowed such fee as the Judge may think right, to be paid by the practitioner, or by the solicitor having carriage of the proceedings, upon the certificate of the clerk of the peace."

Testimonials.

We have been favoured with some batches of testimonials, signed by all the teachers at one of our great London Schools of Medicine. We never before fully appreciated the power of language to conceal the thoughts of the writers of these testimonials. Surely not one of the gentlemen who wrote these effusions believed a word of what he was writing. It is the custom to give such credentials to all students. There is a recognised formula, for the competent and the incompetent. The lazy student and the hard-worker receive the same form of words, setting forth their abilities, their fitness for any public appointment. There is a positive dishonesty, or want of morality about this system, that is disheartening to think about. Has medicine a tendency to lower the moral tone? An American journal has recently published a leading article deliberately stating that it has such an effect. These testimonials give colour to the thought. We would ask the teachers to consider the responsibility which rests upon them in distributing broadcast these untruths. We feel tempted to devote a whole page to copies of one set of testimonials, leaving out name of recipient, but putting in names of

the surgeons and physicians who have given them. If a young man of 22 possesses such transcendent abilities, knowledge, skill, tact, as are set forth in these *testamurs*, then he is Heaven-born, and not of this earth. For the present we shall keep them, but shall be glad if our readers will furnish us with any samples of this kind of thing, so that we may, on some future occasion, give a death-blow to the system.

Hair Pomades and Skin Diseases.

A LARGE number of cheap hair pomades are in common use, and we have reason to know that their habitual application is likely to induce serious mischief in the hair, in some cases producing eruptions on the scalp. There are some well-known brands of hair pomade, like vaseline, &c., in the market, but they are expensive, as the material of which they are made is good, and there is some cost in their production.

For the cheaper kinds, all kinds of refuse are used, fats and oil from diseased animals. We need not wonder, then, if there be a slight abrasion on the scalp, that these unwholesome productions should produce serious mischief. Various perfumers are used to conceal the true odour of these pomades, so that the test of smell is set at fault and is no criterion as to their character.

We would recommend all who use hair pomades or hair washes to obtain prescriptions and have them made up by some respectable chemist; they will thus have a certain kind of guarantee as to the purity and nature of what they are using.

The Charge of Branding an Apprentice.

LAST week, in the Queen's Bench Division, Dr. Maunders was found guilty of having committed an assault on a boy named Devenish by burning him with a hot poker, and damages were assessed by the jury to plaintiff at £80. The incident has an important interest for medical men, so that it may be desirable briefly to recapitulate the facts of the case. The plaintiff was found secreted in the bedroom of his master's daughter, and on being ordered to leave the room, he paid no attention to the command, either being or pretending to be in an unconscious condition. The defendant, Dr. Maunders, was then summoned by the boy's employer, and having been supplied with a heated poker, applied it, as he says, once, and lightly, as the plaintiff asserted, frequently, to the legs of the latter. At any rate, the desired effect was produced, and whether shamming or real, the fit disappeared, and neither then nor immediately after was any complaint of severe ill-usage uttered by the boy. According to his evidence in court, however, he was frequently and seriously injured by the hot iron, and in proof, exhibited numerous scars on different parts of his legs. These were described by Mr. A. T. Norton, of St. Mary's Hospital, who was called as an expert witness, as discolourations which might have been caused either by burning or blistering, and he noticed one mark $4\frac{1}{2}$ inches long on the outer part of the calf which might have been caused by blistering, but which a poker could hardly have produced, since it would not lie that length along a rounded surface. Conflicting, however, as the testimony was, the jury were satisfied of its truth in certain points, as their verdict sufficiently

shows; and in the light it throws on the possible danger practitioners may incur by heroic treatment of malingering or hysterical persons, it behoves us to utter the warning it conveys. More than once recently, results of proceedings instituted against medical men in criminal courts have emphasised the necessity for avoiding even the appearance of assault in such cases; and much as those who recollect the traditions that guided medical practice a generation ago may be inclined to ridicule the idea, it must none the less be accepted that no proceeding is justifiable on the part of a doctor that would not be equally legitimate if pursued by a layman, so far, that is, as physical treatment is concerned. There are certain cases, it is true, that require to be met by prompt and energetic coercive measures, and in every surgeon's experience these are of constant occurrence. Such, for instance, are those examples of hysterical mania, which the douche will alone control; such an one also was that submitted to treatment by Dr. Maunders. The threat of physical suffering to be inflicted is, as a rule, sufficient to influence the majority of these patients. In the eye of the law Dr. Maunders erred in applying it when he found the mere threat unavailing, and inasmuch as by so doing he contravened the spirit and letter of the law, he cannot be said to have been unduly punished. His case, however, will, we are sure, be a warning for the future, both to him, and to all others placed in a like position.

Death of Professor Schwann.

THE eminent biologist of world-wide renown as an original investigator in the domain of histological anatomy, Theodore Schwann, has just died, aged seventy-two years. Few men among living authorities in science have done more to advance the limits of our knowledge than was accomplished by him during the active years of his life; and a feeling of universal regret will be experienced that another, and that his, name is added to the long roll of our recent losses in this direction.

Mr. Keith and Listerism.

IN reference to the sensation produced at the International Medical Congress by Mr. Keith's open abandonment of Listerism, a correspondent of the *New York Medical Record*, signing himself "H. O.," brings certain charges against the Scotch surgeon which are certain to evoke from him either an explanation or a denial. According to "H. O.," Mr. Keith omitted to inform the members of the Congress that in the twenty-five cases, of which five terminated fatally, and which were the last cases treated by him on the principles of Listerism, he employed a solution of carbolic acid *one-tenth stronger* than that prescribed not only by Lister, but by the commonly adopted proportions of the spray. It will be remembered in this connection, that of the fatal cases which determined Mr. Keith's rejection of Listerism, three succumbed to carbolic poisoning, and one died from renal hæmorrhage; and in the light thrown on them by "H. O.'s" assertion, no surprise will any longer be felt at the result. We do not wish to reproduce the expressions made on Mr. Keith's conduct in this matter by our American contemporary's correspondent, but we cannot conceal the importance of his communication on the

supposition that his information is as well substantiated as he declares it is. The blow dealt against Listerism by Mr. Keith has been admitted on all hands; and if it can be proved to have been unfairly delivered, this will explain what it has puzzled us, among many others, to understand. Thus challenged, it remains for Mr. Keith to reply to the charge, and we trust he will be quick to do so.

A Danish Scheme of Anti-vivisection.

THE Danish Society for the Protection of Animals forwards a circular offering prizes of 2,000 and 1,000 francs respectively for essays on the subject of replacing recently killed for living animals in prosecuting physiological investigation:—"The essays may be written in the Danish, Swedish, English, French, or German languages; they must be clearly and legibly written, signed with a motto, which is also to be placed on an accompanying envelope, containing the name and address of the writer. These are to be forwarded before the 1st September, 1882, to His Excellency, Mr. A. de Haxthausen, President of the Danish Society for the Protection of Animals, at the office of the Society, Copenhagen." The circular proceeds to say:—"Our Society is only too well aware that the claims of humanity are not to be satisfied by these means as extensively as it could wish. It will, however, feel itself richly rewarded if its efforts result in diminishing the number of experiments in which animals are subjected to great and lingering agony. In this earnest hope we respectfully request all humanely-disposed scientific men of every country in the world kindly to comply with our invitation."

We do not doubt the executive officers of the Society are actuated by most excellent motives, or that they will receive many praiseworthy communications. But we do unhesitatingly aver a belief that no real advantage to scientific inquiry is likely to result from the proceeding, or that British anti-vivisectionists would permit such means of pursuing physiological study ever to exist unchallenged.

The Election of a Professor of Anatomy in the Irish College of Surgeons

Took place on Thursday last. There were ten candidates—viz., Dr. Abraham, Curator of the College Museums; Dr. Allen, Senior Demonstrator of Anatomy in Glasgow University; Dr. Anderson, Demonstrator and Assistant to Professor Redfern, in Belfast College; Dr. Charles, Lecturer on Practical Physiology in St. Thomas's Hospital; Dr. Cunningham, of Edinburgh; Dr. Knott, Senior Demonstrator in the School of the Irish College; Dr. Ledwich, Lecturer on Anatomy in the Ledwich School; Dr. Reid, Senior Lecturer on Anatomy in St. Thomas's Hospital; Dr. White, Demonstrator in the Sheffield Medical School; and Dr. Young, Lecturer on Surgical Pathology in Owens College. As required by the bye-laws of the College, seven of the Council were selected by lot—viz., Messrs. MacNamara, Porter, Mapother, Butcher, Denbam, Swanzy, and MacDonnell; and the testimonials of the candidates were taken in charge by them. After the usual private deliberation,

they announced that they had elected Dr. Cunningham, who was thereupon declared to be the new Professor. Dr. Cunningham is very highly distinguished. He is an M.B., M.Ch., and M.D. (with 1st honours) of the University of Edinburgh, 1874, and gained a gold medal for his thesis. He is also F.R.S.E. His present position is that of Senior Demonstrator in the University of Edinburgh, in which capacity he has administrative charge of the Practical Anatomy Department in the University School. He delivers, jointly with Professor Turner, a winter course of lectures on Topographical Anatomy; and is solely responsible for a similar course on some more special branch during the summer session. Last winter the students attending the Practical Anatomy class numbered 666, and during the past summer, 236. He is also Lecturer on Physiology to the Royal Veterinary College in Edinburgh, since 1876. Dr. Cunningham's public writings on anatomy and histology are very numerous, and of the highest class; and his attainments and capacity as a teacher are vouched for by many of the leading anatomists and physiologists, not only in the United Kingdom, but on the Continent. The appointment is one to which no exception can be taken, inasmuch as Dr. Cunningham occupies a professional position to which few candidates could claim to have attained. We congratulate the College on having secured his services, which cannot fail to be of inestimable value, not only to its school, but to the progress of anatomical and histological science in Ireland.

Provincial Hospitals.

THE method of electing surgeons to our provincial hospitals demands reform. It is most humiliating to the candidate, and unprofessional in every sense. Custom has, however, sanctioned it; custom must, however, alter. In every provincial town there is a general hospital, supported by voluntary contributions. Every guinea subscriber has certain privileges, amongst them being a vote at the election of the honorary surgeons or physicians. There may be a thousand subscribers; some may have more votes than others. When the surgeon offers his services to the institution he has to canvass all the subscribers; he has to ask the favour of the vote and interest of may be a thousand persons. He makes a regular canvass, and has to go, cap in hand, from door to door, on the humiliating errand of asking for votes. This is the first step. In the next place, he has to advertise in the local papers; he has to blow his own horn. If there are a number of candidates he has to put an extra degree of wind into his petition for election, to blow his horn louder than his competitors. He sets forth his qualifications in full, where he has been educated, what prizes he has taken; in fact, he gives a *resumé* of his life history, and backs this up with testimonials. If we compare all their addresses, there is a wonderful degree of similarity in them; and if we look at their testimonials we shall find that they are all framed on the same model. The puzzled subscriber or elector does not know how to decide between the candidates; they are all so clever—Coopers, Pagets, Fergussons. He very wisely throws the testimonials into the waste-paper basket, and

gives his vote to his own doctor, if he is a candidate, or to the man he knows out of the batch of candidates. This state of affairs should be altered. There should be a small elective body selected from the bulk of the governors. They should have the power of filling up all vacancies. Canvassing should be forbidden so strictly that it should be a bar against election. Public advertising should be done away with. It does not add to the dignity of the profession to read the addresses of medical men side by side with the advertisements of the vendors of patent candles, cheap teas, or blacking. The candidates may be permitted to send out private circulars to the small elective body, which is all that is required.

Dispensary Drugs and Special Medicines.

In the Irish Supplement to our present issue we publish an important correspondence between Dr. Wallace, together with other medical officers of the Parsonstown Union, and the Local Government Board for Ireland. The instructions printed on the newly revised Drug List issued by the Local Government Board set forth that medical officers who required any medicines not named in the list should make a special requisition for them. In accordance with this order, Dr. Wallace and others asked for certain drugs, which, however, the Local Government Board objected to being supplied, on the ground that "the list of medicines is sufficient to meet the reasonable requirements of medical officers." To this Dr. Wallace replied that—

1. The prescribed list contains no pepsine, nor any preparation of free phosphorus, nor of the hypophosphites, and excludes articles in such every-day use as vaseline, boracic acid, pancreatic emulsion, iodoform, salicylic acid, non-official pearl-coated pills, india-rubber bandages, and the like. These and other articles are so valuable as remedies, and so universally used, that I fail to see that they are outside the "reasonable requirements of medical officers."

2. It is well known that the medicines contracted for are supplied at such low prices as to destroy confidence in their strength and purity. The only way open to medical officers to get medicines in which they have confidence is to order them as specialities, with the name and under the seal of some maker of well known and good repute.

The Local Government Board replied that proprietary and patent medicines have been purposely omitted. Many of them are of extremely doubtful value, and owe their reputation principally to a system of constant advertising. However, if any even of those medicines be desired by a medical officer in any special case, it is within the power of the guardians to order them on special requisition.

The effect of this letter is to make the guardians the judges of the necessity for any medicinal agent required by their medical officer, which, we need hardly say, they are totally incompetent to decide upon. It would be impossible and improper to restrict Irish Poor-law medical officers to the preparations named in the British Pharmacopœia, which, as Dr. Wallace, points out, omits a multitude of medicines in every-day use by all practitioners, and contains a multitude which are almost never

prescribed. Of course, Poor-law medical officers should exercise a reasonable discretion, and not order expensive drugs except for good reason; but where such reason exists, it is their right, as well as their duty, to have all the most efficacious means at hand wherewith to treat their patient. If the guardians or the Local Government Board refuse the means of treatment, they must accept the sole responsibility for the life of the patient.

Lectures at the Royal College of Surgeons of England.

THE following lecture arrangements have been made at this College for the present year:—

Professor Parker will commence a course of nine lectures on "The Morphology of the Mammalian Skull" on Monday next. Professor Flower will then deliver nine Lectures on "The Anatomy, Physiology, and Zoology of the Edentata," commencing on Monday, February 27th. In June, Professor Hutchinson and Mr. Yeo will complete the lectures for the year, the former by the delivery of a course of six lectures on "Temperament, Idiosyncrasy, and Diathesis in relation to Surgical Disease," and the latter by a course of three lectures, the subject of which has not yet been decided.

These lectures will be delivered on Mondays, Wednesdays, and Fridays, at 4 o'clock p.m. precisely each day.

Prosecution for Dissemination of Puerperal Fever.

At the recent Assizes at Maidstone, Caroline Tomsett, a midwife at Tonbridge, surrendered to take her trial for the manslaughter of a woman named Morgan. The prosecution was undertaken by the Treasury. The offence imputed to the prisoner was that, by negligence and want of proper precaution, she had infected the deceased with puerperal fever, and had thus, by culpable negligence, caused her death. On August 25th last the prisoner attended the deceased in her confinement, and two or three days afterwards she was attacked with the fever, which proved fatal on September 1st following. Dr. Stanford, who attended the deceased, was examined. He believed that the prisoner was very careful with her patients. A fortnight or three weeks before August 25th he told her that he feared she was carrying some septic poison about with her, and advised her to wash her hands in carbolic acid or some disinfectant, to have her clothes disinfected in the oven at the infectious hospital, and to be otherwise careful. He did not then know that she had been attending patients suffering from puerperal fever. Dr. Coates deposed that the prisoner asked him how long a time it ought to be before she attended another case of confinement, and that he told her she should not go near another case for at least a month. Mr. Justice Grove, in summing up, left it for the jury to decide whether the prisoner had knowledge that the other women she had recently attended had been suffering from the fever, and if so, whether she had been guilty of criminal carelessness in acting as she did. The jury, after some deliberation, returned a verdict of "Not guilty."

The Vaccination Controversy.

THE next monthly conference of the London Society for the Abolition of Compulsory Vaccination will be held in Steinway Hall, 15 Lower Seymour Street, Portman Square, Marylebone, on Friday evening, Feb. 3rd, at 7.30 o'clock, when the chair will be occupied by Dr. Andrew Clark, and a paper read by Dr. W. B. Carpenter, C.B., entitled, "The Increase of Small-pox Mortality in London during the Year 1880, without any corresponding Increase in other Parts of the Kingdom, a Reason—not for a Repeal of the Compulsory Vaccination Act, but for increasing the Efficiency of its Operation." Medical men holding different views on this vexed question have been invited.

The Compulsory Education Act.

How many years will it be before we shall be able to sum up the value of the present system of compulsory education, to estimate its gains or its losses, to prove its results as seen in the elevation of our national life?

How many Faradays, Newtons, Herschels, Huxleys, Tyndalls will it produce? Shall we have a large development of genius, or a number of harmless mediocrities, as the result of our higher Board schools? Time, the daughter of Truth, must unfold the answers to these queries; meantime we may direct attention to one aspect of our educational system—viz., the compulsory education of children of five years of age. If the Kindergarten method be adopted with children of five, no harm can result from their attendance at school, but if they are trained and taught under the ordinary system of education, then harm must ensue, and we shall reap in the future a harvest of insanity, from the over-working and destruction of cerebral matter in a state of development. This is not an imaginary statement. We are not alarmists. Children of five should not be forced; their brains should not be disturbed or exhausted by set lessons; their physical development at this period is of more importance than their mental development. Many parents take a pride in the precocious talent of their offspring, but in after years they regret that they did not understand how dangerous it was to prematurely develop such an organ as the brain. Their hopes have been disappointed, for the promising boy of five has been at twelve a dull, heavy, stupid lad, and each year has added to their discomfort, by proving that as manhood was reached, the intellectual development has retrograded, purely in consequence of the destructive degeneration or wasting of the brain, in early childhood, by forced lessons—efforts of memory in reciting long pieces of poetry, or doing arithmetical problems. The lesson we desire to impress on parents is a simple one. Up to seven or eight years of age let the child's physique be the chief care of the instructor. A healthy frame is a priceless boon. If the general physique is good, the brain will participate in all the advantages resulting from this condition; the power to learn will be all the greater; and with this power the child of seven will make up for the two years lost by a quicker acquisition of knowledge.

Putting it in a simpler form, we may say, that if a child of five knows how to read, and another child aged

seven only knows the letters of the alphabet, the latter will soon catch up the other child, will soon read better, and excel in the acquisition of whatever they are both studying. The Act presses hardly upon the child of the working man. The School Board attendance officer visits his house if his child aged five does not attend, whilst the same officer does not visit the better classes. Compulsory education will benefit the working classes. Education is provided very cheaply for them; it is perhaps as well that it should not be without its alloy, and that those who have to pay for the Education Act should have some privileges.

The Parkes Museum of Hygiene.

AN important meeting of the Executive Committee of the Parkes Museum was held on Friday last, Professor Berkeley Hill, F.R.C.S., in the chair.

The Curator, Mr. Mark H. Judge, as Secretary of the recent International Medical and Sanitary Exhibition, presented the final report of the Exhibition Committee, which, after giving a detailed account of the origin and success of the undertaking, concluded as follows:—"The work for which the Exhibition Committee were appointed having now come to an end, they have the satisfaction of handing over to the Executive Committee of the Museum the sum of £933 11s., together with furniture and fittings to the value of £100, while contributions to the Guarantee Fund to the amount of £86 19s. have been transferred to the Parkes Museum Building Fund, making the financial result of their labours a profit to the Parkes Museum of £1,120."

The Honorary Secretary, Dr. G. V. Pore, read a communication from the Council of University College, in which that body agreed, with some modifications, to proposals which had been made on behalf of the Museum to the Council of the College in reference to the erection of a building for the Museum. After a long discussion in which Professor Berkeley Hill, Professor Hayter Lewis, Dr. W. R. Gowers, Professor Corfield and Mr. Rogers Field, took part, the modifications suggested by the Council of University College were accepted, and it was resolved that steps should be taken to obtain the funds necessary for carrying out the scheme, which embraces: 1st. The building of an addition to the north wing of the College for the purposes of the Museum. 2nd. An endowment for the maintenance and management of the Museum. 3rd. The Museum to be open free to the public, and to be placed on a somewhat similar footing to the University College Hospital, i.e., to be autonomous with due representation of the Council of University College on the Executive Committee of the Museum. It is estimated that £30,000 will be required to thus permanently establish the Museum as a national institution. Towards this, Mr. Thomas Twining, of Twickenham, had written to say that he would subscribe the sum of £100, if one hundred promises of a similar amount were obtained. Promises of subscriptions may be sent to the Curator, at the Parkes Museum, University College, Gower Street. Subscriptions may be paid to the account of the Parkes Museum, at the Union Bank, Argyll Place, Regent Street.

Surgical Society of Ireland.—Presentation to Dr. B. W. Richardson.

THE meeting of the Society on Friday night last witnessed the ceremonial of a presentation to Dr. Benjamin Wills Richardson, Chairman of the Court of Examiners of the Irish College of Surgeons, on his retirement from the office of Hon. Sec. of the Society. The presentation was a handsome silver tea and coffee service and salver, subscribed for by the members of the Society, and it was presented to Dr. Richardson by the Vice-President of the College, Dr. Barton, who accompanied the gift by a warm expression of the good feeling of the Society towards its retiring executive officer. A report of the entire proceedings, with Dr. Richardson's reply, will appear in an early issue, but we cannot allow the occasion to pass without joining in the expression of esteem to which the Vice-President gave utterance. Dr. Richardson served the Society for very nearly a quarter of a century, having been appointed its Hon. Sec. on the 19th of Nov., 1857, and during all that time his interest in its welfare never flagged.

It is very satisfactory that he remains among us, and that he can feel that his professional brethren are not ungrateful.

WE publish in our columns of this day the first portion of a very interesting and able paper—"A Retrospect of Sanitation of former years as contrasted with that of the present day," by Dr. Davys, of Swords, read by him at a recent meeting of the Public Health Medical Officers' Association in the College of Surgeons.

THE rates of mortality last week in the principal large towns of the United Kingdom per 1000 of their population were:—Derby 15, Bolton, Birkenhead, and Leicester 16, Portsmouth, Edinburgh, and Bradford 18, Bristol, Halifax, Wolverhampton, Newcastle-on-Tyne, Cardiff, Birmingham, Leeds, Norwich 20, Sunderland 21, Hull, Salford, Manchester, London 22, Preston and Liverpool 24, Sheffield and Glasgow 25, Brighton, Blackburn, and Plymouth 26, Nottingham 29, Huddersfield 31, Oldham and Dublin 33.

AN old and valued contributor to our columns, Mr. George Macilwain, F.R.C.S., has just died at the ripe age of 85. Since retiring from active practice in London, he has resided at Matching, in Essex, where he peacefully passed away last week, full of years, leaving behind in the memories of all who knew him the knowledge of a well-spent life, an unswerving honesty of purpose, and a love of his profession which few have excelled. Mr. Macilwain was one of the oldest members of the English College of Surgeons, his diploma dating so far back as 1818. He did not attain his Fellowship till 1843.

THE highest death-rates per 1000 in the large towns last week were—from scarlet fever 4.9 in Hull, 3.5 in Sunderland, and 3.0 in Nottingham; from whooping-cough, 2.0 in Salford, and 1.8 in Sunderland; from measles, 3.5 in Norwich, and 2.7 in Preston; and from "fever," 1.8 in Birkenhead. In Hull 15 more fatal cases of scarlet fever were recorded, raising the number re-

corded within this borough since the beginning of July last to 690. The 42 deaths from diphtheria included 17 in London, 10 in Glasgow, 5 in Portsmouth, 3 in Nottingham, and 2 in Sunderland. Small-pox caused 23 more deaths in London and its suburban districts, and one in Hull.

IN the principal foreign cities the rates of mortality per 1000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 48, Bombay 31, Paris 27, Geneva 23, Brussels 24, Amsterdam 25, Rotterdam 24, The Hague 28, Copenhagen 23, Stockholm 21, Christiania 16, St. Petersburg 47, Berlin 24, Hamburg 28, Dresden 26, Breslau 29, Munich 28, Vienna 29, Prague 31, Puda-Pesth 35, Naples 28, Turin 34, Venice 32, Alexandria 33, New York 32, Brooklyn 24, Philadelphia 24, Baltimore 26. No returns were received from Madras, Rome, and Lisbon.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

ABERDEEN ROYAL INFIRMARY.—The Committee of Management of the Aberdeen Royal Infirmary had before them on the 25th ult. a letter from Dr. Rattray, surgeon-superintendent, intimating his resignation, on account of advancing years. Dr. Rattray has filled this office for upwards of forty years.

MONTROSE COMBE LECTURES.—Dr. Stirling delivered the last lecture of this series on the 24th ult., in the hall, Montrose. The subject of the lecture was "Ventilation and Respiration," and it was illustrated by a large number of experiments. The attendance at all the lectures has been uniformly large, and the interest has been kept up throughout. Cordial votes of thanks were given to the Combe trustees, and Dr. Stirling remarked that if people would realize to what extent man is dependent on, and modified by, his physical surroundings, the teaching of George Combe and the Combe Lectures would not be in vain.

FEVER EPIDEMIC IN LANARKSHIRE.—Some weeks ago an outbreak of fever, which has now assumed the proportions of an epidemic, took place in the village of Crossford, in the Upper Ward of Lanarkshire. The disease comprises typhoid fever, diphtheria, and scarlet fever. The malady is said to be spreading along the Clyde side, as some cases have recently appeared in the village of Rosebank. Several cases of death took place in Crossford, where a person is ill in almost every house. The public school was closed about a month ago, and now the head teacher is prostrated with fever. The places affected are in the parish of Lesmahagow, and there is no doctor nearer than Lanark and Carluke, each of these towns being about four miles distant. The water supply is derived from natural springs.

OPENING OF A NEW HOSPITAL AT NEW MONKLAND.—For some years back the hospital at the New Monkland Poorhouse, from its overcrowded state, low ceilings, small, ill-ventilated wards, and the want of sanitary appliances, was found to be far behind the requirements of the time. Mr. Malcolm M'Neill, the visiting officer of the Board of Supervision, in a report issued some time ago, stated:—"The hospital appears to me to possess no single characteristic in harmony with modern views as to the treatment of

the sick." Such a state of matters existed until last week, when the sick paupers of this parish were removed to a new hospital, with greatly improved accommodation. The whole scheme has been devised and carried to a most successful issue by Dr. Robertson, the Chairman of the Board, who personally visited several of the most important modern hospitals in connection with poorhouses.

APPOINTMENT TO A DUBLIN CHAIR OF ANATOMY.—The recognition of talent denied at home is not unfrequently avowed abroad. Edinburgh medical men have a good deal to complain of in the matter of what might be called foreign teachers. We are glad to be able to record that the abilities of Dr. D. J. Cunningham have been recognised in Dublin by his appointment to the Chair of Descriptive and Practical Anatomy in the College of Surgeons there. For the remainder of the present session Dr. Cunningham will continue in his present position in the University of Edinburgh.

EDINBURGH ASSOCIATION FOR INCURABLES.—The annual meeting in connection with the Longmore Hospital for Incurables, Salisbury Place, was held, on the 26th ult., in the saloon of the Royal Hotel. The attendance was a good one, for the most part composed of ladies. Mr. T. R. Buchanan, M.P., presided. The secretary, Mr. J. T. MacLagan, C.A., read the report, which was highly satisfactory.

GREENOCK.—ALLEGED IRREGULARITIES AT THE INFIRMARY.—At a meeting of the Ratepayers' Committee, on the 25th ult., Mr. Thomas Mitchell, in the course of a long speech, referred to the working of the Public Health Act in Greenock, and expressed dissatisfaction with several of the officials connected with its administration. Speaking of the Infirmary, he said that people now felt horrified at the idea of being taken to that place when suffering from infectious disease, because it was reported that in that model institution the bodies of the dead got either lost, mislaid, or, in some way or other, were missing, and were never found again. These are certainly strange accusations, and the matter ought to be cleared up.

THE EDINBURGH TOWN COUNCIL AND THE LATE SIR R. CHRISTISON.—On hearing of Sir R. Christison's death, the Lord Provost directed that a meeting of the magistrates should be convened. A meeting was accordingly held on Friday, January 27th, when it was resolved to record an expression of the public loss which had been sustained in Sir Robert's death, and of sympathy with his family. It was further resolved that, if agreeable to the family, the Corporation should officially attend the funeral. In the course of the day, intimation of the acceptance of this offer was received. Accordingly, the Lord Provost, magistrates, and Council, in their robes of office, will take part in the obsequies, which, we understand, have been fixed for today (Wednesday).

Literature.

ON CANCER: ITS ALLIES AND OTHER TUMOURS. (a)

WHEN the surgeon of a cancer hospital writes a book on the speciality of his institution, we may well expect (to use the language of the ancient divines) a *concio ad clerum*; and it is proportionally disappointing to be treated to a *concio ad populum*, and that of the most commonplace character.

(a) "On Cancer: its Allies and other Tumours, with Special Reference to their Medical and Surgical Treatment." By F. Albert Purcell, M.D., Surgeon to the Cancer Hospital, Brompton. London; J. and A. Churchill. 8vo. Pp. 311

There is not in the entire book anything that is new, or that is not to be found in ordinary text-books. If this were all it would be bad enough; but we regret to be obliged to add that voluminous extracts are taken, sometimes with the alteration of a few words, and sometimes without any alteration at all, from the lectures on the same subject, published by Mr. Butlin, F.R.C.S., in the *Lancet* of last year. The resemblance between Dr. Purcell's description of epithelioma and that in Dr. J. Henry Green's manual (one of the best little books that ever was written) can hardly be believed to be accidental. To have copied from some obscure work would have been regrettable, but how anybody could copy from the *Lancet* of last year, and expect not to be found out, is beyond our comprehension; we can only imagine that the author thought that nobody would read the book, but that he would be remembered as a specialist writer. About thirty years ago the late Lord Beaconsfield was detected in a similar plagiarism, and *Fraser's Magazine* published (under the title of "The New Curiosities of Literature," by the Right Hon. Benjamin Disraeli, M.P.), a long extract from one of his novels (as well as we can remember, Vivian Grey), and in a parallel column the exact words already published by another author. Since that time we have seen nothing like this, except in the case of a well-known treatise on anatomy, and we trust we shall see no more of it. We are unwilling to speak severely, but we cannot avoid expressing our deliberate belief that Dr. Purcell's book is not written for the purpose of advancing medical science, but simply to advertise him as a specialist. The book is well brought out, and the wood-cuts are neat and distinct.

Correspondence.

"THE DENTAL DIPLOMA TRAFFIC."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Permit me to make a few observations which are elicited by your article on the above subject, which appeared in your issue of the 25th inst.

I will pass by your analysis of the educational attainments and occupations of the 2,500 candidates for the dental diploma, leaving it to those aggrieved the fighting of their own battle; but when you state that "the only tests of fitness required are the readily-obtained signatures of one or two unknown persons, and an examination which we believe to be utterly unreliable as a proof that the candidates have any sound knowledge of dentistry," I must challenge your statement. In the first place it is manifestly incorrect to describe the fellows of any college, professors, eminent dentists, &c., as "unknown persons," and, in the second, it is equally incorrect to stigmatise an examination as "utterly unreliable" in face of the fact that nearly 40 per cent. are rejected. No doubt the examination, like most mundane matters, is capable of improvement. It should be made more thoroughly practical. Candidates should be tested more searchingly as to their knowledge of dentistry. They should be introduced to a dental hospital, with a view to ascertain their practical acquaintance with the treatment of diseases of the mouth, dental operations, fillings, &c. Candidates should furnish evidence as to their intimacy with the *terms* used in dental pathology and surgery. They ought to be able to define the difference between a tumour and an hypertrophy, and not describe either in such horticultural phraseology as "a cauliflower growth."

As to the abolition of examinations *sine curriculo*, I consider such a step in my humble opinion would be premature, and in many cases unjust in the absence of proper arrangements (so far as Dublin is concerned) for the carrying out of a curriculum, the dental portion of which is still in embryo, if not in nubibus.

In conclusion, allow me to say that the *Medical Press and Circular* has acted a somewhat inconsistent part throughout the discussion of this matter. When efforts were made to elevate the status of dentists by making the L.D.S.T. a supplementary diploma, your journal was lukewarm, if not positively antagonistic, and its sudden and almost feverish anxiety for the dignity of the dental profession is rather puzzling, and looks like "locking the stable when the steed is stolen."

I remain, Sir, faithfully yours,

FRANK THORPE PORTER, F.R.C.S.I.

15 Upper Merrion Street.

[Our correspondent is probably aware that the only credentials of a candidate for an Irish dental diploma are the recommendations of two medical practitioners (Heaven knows easily obtained) and two "dentists of repute," whatever that rustic phrase may mean. As a matter of fact, we know from the minutes of the General Medical Council that one Dental Licentiate of the Irish College was expelled as an obscene quack, who had had no difficulty in producing these evidences of respectability, and—considering that no college can possibly have any knowledge whatever of the "repute" of the recommending dentists—we may be excused from believing that these tests of decency are altogether illusory. As regards the examinations, we have nothing to say. They are possibly as good as any such examinations are likely to be under the circumstances, but our correspondent himself admits that they are faulty, and no one will suggest that they are of themselves, and without curriculum, a sufficient test of knowledge. It is notorious that they are not, and that a host of persons who can neither spell, read, write nor practise dentistry, are admitted Licentiates in Dental Surgery under them.]

The *Medical Press* is, and has always been, adverse to requiring a surgical degree for the practice of dentistry. For it would be as reasonable to require an engine-driver to take a degree in mechanism and experimental science. Registered dentists—not to say Licentiates in Dental Surgery—ought to know as much dentistry as will prevent them killing or mutilating unsuspecting patients, and practising in the domain of surgery which is comprehended under the name. We ask no more, but we insist that neither colleges, courts of examiners, nor "grinders" should be allowed to make money by the traffic we have denounced. The dental surgeons are evidently weak-kneed, but the question is one affecting the surgical profession, and we must therefore continue to protest.]

THE DUBLIN CORPORATION AND THE CONVALESCENT HOME.

In reference to the abandonment of the projected Convalescent Home for Infectious Diseases in Dublin, an editorial note recently appeared in these columns in which it was pointed out that the movement had failed by reason of the little encouragement given to it by the Dublin Corporation. In the article in question we expressed our surprise that, though the Corporation could find plenty of money as a subvention to enable persons of insignificant commercial position to take the Lord Mayoralty, it could not provide funds to establish for the sick poor of Dublin a refuge on their dismissal from the Fever Hospital.

Respecting the comments of the *Medical Press*, the Lord Mayor wrote a letter to the *Freeman's Journal*, which we have thought it necessary to answer by the letter which follows his Lordship's below.

From the LORD MAYOR to the EDITOR.

SIR,—In your issue of the 11th inst. there is an article entitled "The Convalescent Home for Infectious Diseases in Dublin." After quoting the resolution of December, 1881, recommending the handing-over the funds collected to the Cork Street Hospital, you make the following remarks:—

"But the Dublin Corporation saw no chance of a possible row likely to arise out of such a movement, and did not anticipate that a convalescent home would afford much opportunity for family jobs, so it received the proposal coldly."

And further on you say—

"But it would not trouble itself with the spread of infectious diseases in the city, except, indeed, so far as to compel the doctors to do the work for nothing."

And finally you say—

"We regret the failure of the attempt to establish the home, but we think the promoters must have known little about the Corporation when they undertook the hopeless task of interesting them in the sick poor."

These statements are full of misrepresentations and utterly devoid of truth. Instead of receiving the proposal coldly, the proposal was made by the Corporation. The history of the question is this:—After the small-pox epidemic in January, 1879, on consideration of a letter from Mr. E. D. Gray, M.P., Chairman of the Public Health Committee, the Municipal Council on January 27th adopted the following resolution:—"That the letter be referred to the Public Health Committee, with an intimation that this Corporation would be disposed to consider in a liberal spirit any proposal that it should aid in the establishment of a convalescent home for the use of patients recovering from infectious diseases." The Council advised conference with the heads of hospitals. Several conferences were held. On February 22nd a public meeting was held at the Mansion House under the presidency of the Lord Mayor. At that meeting the principal resolutions were proposed and subscriptions given by members of the Corporation.

In July, 1880, to further encourage the project, I proposed, and Alderman Harris supported, the following resolution, unanimously adopted:—"That this Council is willing to support liberally by capitation grant or otherwise the maintenance of a convalescent home, provided the Corporation be adequately represented on the governing board."

The Mansion House Committee, largely composed of members of the Corporation, continued their labours. £4,000 were required. We could not get £1,000.

The two learned professions of medicine and law did not give £100 between them. Great doctors put down their names on committee, but gave no money. Persons of great station subscribed, but never paid a penny. The minutes are before me, and the lists of the unpaid on my desk. And thus, not from any failure on the part of the Corporation, who originated and were prepared to sustain the movement, the matter fell through owing to the absolute neglect of the great professional and wealthy classes in Dublin. So far for the complete falseness of your charge of indifference.

As to the statement about family jobs. There is not at this moment one person holding any corporate situation in any way connected with members of the body. Our medical officer—the best paid of all—is wholly distinct in family from all, and in religion and politics from the majority of the Corporation. I am acquainted with great towns in England, where, to my knowledge, highly paid officials are near relatives of the members of the Council. With regard to your last libel on the Corporation, it is more false than any. You accuse them of want of interest in hospitals. The writer of your article, if, as I suspect, he be a person resident in Dublin, knew when he penned this statement that the Corporation pays £4,000 a year towards the hospitals; and he knows that the fashionable township whose poor they accommodate don't subscribe one shilling towards them.

Therefore, Sir, all your statements are untrue, and I have to request the insertion of this letter in the paper which was so rash as to publish them.

I have the honour, Sir, to remain,

Your obedient servant,
CHARLES DAWSON, M.P.,
Lord Mayor of Dublin.

Mansion House, Dublin,
Jan. 16th, 1882.

The EDITOR to the LORD MAYOR.

SIR,—I learn from the return to me of a printed slip, which had been sent to our London office a week ago, that the Lord Mayor has addressed to you a letter in which he takes exception to some remarks in the *Medical Press* as to the attitude of the Corporation towards the Convalescent Home for Infectious Diseases, projected some time ago by certain philanthropic citizens, and since abandoned for lack of support.

I should not consider it necessary to reply to this letter but that his lordship thinks it not unbecoming to assail the professions of medicine and law resident in Dublin of acts amounting to dishonesty, and I, therefore, feel bound to show the citizens that there is no ground for his aspersions, and that the abandonment of the effort to establish the

"Home" was the work of the Corporation alone. I need hardly repeat the arguments used by the promoters of the movement to enforce upon the Public Health Committee the necessity for establishing such an institution. It will be sufficient to say that it was fully proved that infectious disease were habitually spread throughout Dublin by the patients who left hospital saturated with fever poison and returned to their homes because no other refuge for them existed. Now, Sir, under the 155th section of the Public Health Act, the Corporation had for years full power to "provide for the use of the inhabitants of the district hospitals, or temporary places, for the reception of the sick or convalescent;" but up to the time when private persons took up the subject, these powers and the urgent necessity for providing a home were entirely forgotten by Mr. Dawson, then a member of the Public Health Committee, and now Lord Mayor. In the end of January, 1879, the Corporation—who now seek to have credit for the movement—were stirred up by Drs. J. W. Moore and Duffey, and certain other physicians and philanthropists, whose ministrations among the poor had shown them the necessity for such a convalescent home, and a conference was held at the City Hall, at which these gentlemen were made to understand that the Corporation would certainly not undertake either to organise or pay for such an institution, but would grant its august approval, and a small subsidy in case the citizens chose to do all the work and pay most of the cost. This generous policy was further developed at a subsequent public meeting at the Mansion House, when the then Lord Mayor warned the meeting "not to be carried away by the feeling that there was any certainty of the Corporation granting any help to the movement." I need not dwell on the subsequent progress of the movement; it is sufficient to say that it languished and died. The citizens at large felt that it was not their business to do voluntarily and at their private expense the work which the Corporation was authorised to do by Act of Parliament, and was morally bound to do for the benefit of the citizens, and they therefore withheld their subscriptions. Those of the medical and legal professions, whom the Lord Mayor stigmatises as having acted dishonourably in not paying their promised contributions, very naturally kept their money in their pockets when they found that the purpose for which they offered it was—owing to the indifference displayed by the Corporation—impossible of attainment. They were, and are, I assert, still ready to pay towards a Convalescent Home, and I venture—with all the respect due to his lordship's office—to fling back the unjustifiable insult he has put upon the members of my profession in his letter to you.

Now that the Lord Mayor has learned that the Town Council has full power to provide a home—now that my brother-physicians have taught him the vital necessity for such an institution—now that he must be aware (from a recent vote of the Council) that there is plenty of money in the city chest for such purpose as he considers worthy—I invite him to distinguish his mayoralty by the establishment of the Convalescent Home, of which, he says, the Corporation "originated" the idea.

The paltry grants to hospitals of which his lordship makes so much use, in my opinion, no discharge in full of the duty of the Corporation to the sick poor of Dublin. Let that body perform the duty which Parliament imposed upon it, and which the citizens have for years importuned it to discharge, and the Lord Mayor will find that he will no longer have occasion to defend himself in the newspapers by seeking to shift the responsibility of the Town Council to the shoulders of the citizens.

THE EDITOR OF THE "MEDICAL PRESS."

Medico-Legal Intelligence.

THE MEDICAL EVIDENCE AT THE TRIAL OF DR. ABRATH, OF SUNDERLAND.

We have expressed our opinion upon this now notorious case in another column, and content ourselves here with a brief résumé of the medical evidence, with a word on its teaching.

No more serious charge could be brought against a medical man than that of which Dr. Abrath was accused. He was charged with attempting to defraud a railway company by inducing his patient, Michael McMann, to simulate disease and

to fabricate symptoms of injury and its consequences. To complete this fraud Dr. Abrath's turpitude was supposed to be so base that he actually was alleged to have starved his patient, inflicted injuries on him, and ill-treated him in various ways, so that McMann suffered more from the cruelty of his medical attendant than from the accident for which he claimed damages, the motive power of this diabolical fraud presumably being pecuniary gain. McMann was brought to the court on an ambulance. As to his actual condition there could not be much difference of opinion, and we believe it was admitted that he was now suffering from partial paralysis, and that he never would be restored to health. Here is the medical evidence for the defence.

Mr. John Potts, M.R.C.S., Sunderland, said he was an Alderman, Justice of the Peace, and had been Mayor of Sunderland. He attended McMann at Dr. Abrath's request, on September 19, 1880. He was quite free in the case, and was in attendance five days. On examining McMann's back he found a small abrasion, and the patient complained of pain. The abrasion was like a scrub. From its appearance it could not have been caused by a lancet or strong irritants a day or two before he saw it. From what he was told of the accident he thought the body of McMann, coming in contact with the floor of the carriage, might have been abraded. He thought its appearance consistent with the account of the accident. Carbolic ointment was applied. Witness went at different times and found no signs of any secrecy. He came to the conclusion that the man was suffering from partial paralysis in the extremities, which was caused by injury to the spine. From first to last he never had any knowledge of cutting or carving, or of irritants.

Mr. Francis, M.R.C.S., Sunderland, thirty years Surgeon to the Sunderland Police Force, said Dr. Abrath and witness applied the electric test in the presence of Dr. Heath and Dr. Phillipson, of Newcastle, on October 8. On applying the electricity to the right thigh there was a slight contraction of the muscle. When it was applied to the left thigh McMann could hardly bear it, and witness came to the conclusion there was partial paralysis. The electric test was properly applied, and subsequent tests confirmed his opinion. He never saw any attempt at concealment. He called a great many times, but never saw any signs of the man having been drinking. He did not think McMann would ever recover.

Dr. Ridley Dale, Sunderland, gave evidence respecting the application of the electric test.

Mr. Jabez Hogg, London, said McMann was undoubtedly suffering from paralysis in both legs. The objective and subjective symptoms were perfectly consistent.

In cross-examination of Mr. Hogg, the counsel for the prosecution, Mr. Seymour, threw out an imputation against that witness, for which he subsequently expressed regret, and apologised.

His lordship, Justice Mathew, made an observation on this imputation painfully true. "These are the imputations," he said, "that doctors are prepared to say of each other when one of their body is in the box. Suggestions of this kind are made over and over again. It is too bad." (Applause in court.)

These few well-timed words of the learned judge contain the whole gist of this case. Fortunately for the gentleman attacked (Mr. Jabez Hogg), he has been too many years before the profession for his conduct to be called into question, but a similar innuendo might have ruined a young man. Medical men are too ready to impute unworthy motives to their *confidés*, to stand in opposition and pronounce judgment on the opinions of competitors, to become partisans, and take sides in courts of justice; and this unfortunate state of things brings discredit upon the whole profession.

The North-Eastern Railway Company, with all the advantages of capital and influence, were able to secure the services of certain medical men who were prepared to take an oath and contra-lic the evidence on the side of Dr. Abrath. These witnesses would have us believe not only that Dr. Abrath was practising fraud, but that the medical men who were attending the case with him were so incompetent as not to be able to detect this fraud, and thus supported him through ignorance. The jury very justly did not attach the slightest value to the medical evidence given on behalf of the Railway Company. They estimated it at its true worth.

We do not envy the feelings of those professional men now that the verdict has been pronounced. This case would never have been brought into court had not medical men of this class been obtainable. We now come to the first lesson to be derived from the Abrath trial.

1st. We trust that it may lead to some alteration in our method of dealing with medical evidence in civil or criminal cases. We have for years advocated the appointment of medical experts, who shall be nominated by the judicial courts, and remunerated in proportion to the work they perform. They will act as medical assessors. Thus a great opprobrium will be removed.

2nd. Until this change in the law is introduced, we would urge upon medical men the injury they are doing their profession by taking sides in criminal or civil trials.

The great question for Dr. Abrath is, what compensation will

he receive for what he has undergone? Will it satisfy him that a jury of his adopted fellow-countrymen have pronounced a certain number of stereotyped words, that his fellow-townsmen gave him an ovation, and that the court rung with applause when he was acquitted? It would require a large pecuniary *solatium* to pay him for the mental anxiety and the indignities he has undergone.

Obituary.

SIR ROBERT CHRISTISON, BART., M.D.,
LL.D. Edin., F.R.S.E., D.C.L., &c.

THE demise of Sir Robert Christison, Bart., took place on Friday, 27th Jan., at his residence in Moray Place.

The son of Mr. Alexander Christison, for many years Professor of Humanity in Edinburgh University, the late Baronet was born on the 18th July, 1797. He was one of twins, the other being Alexander Christison, who, from 1821 till his death in 1874, was parish minister at Foulden, Berwickshire. Their mother was Margaret, daughter of Mr. Robert Johnston, of Edinburgh. Robert Christison was sent first to the High School, and subsequently attended the Arts classes of Edinburgh University, ultimately turning his attention to medicine. After graduating as Doctor of Medicine in 1819, he betook himself to the schools of London and Paris. In the latter city he became a pupil of Robiquet, the eminent chemist and *pharmacien*, in whose laboratory he worked assiduously. Here, too, he prosecuted, under the celebrated Orfila, that study of toxicology to which he had all along shown a special bent, and in which he was destined to achieve so important results. Shortly after his return to Edinburgh, in 1822, he was appointed to the University Chair of Medical Jurisprudence, in succession to Dr. Alison. This post he occupied till 1832, when he relinquished it to assume the Chair of *Materia Medica*, rendered vacant by the death of Dr. A. Duncan.

The subject of Medical Jurisprudence, when Dr. Christison entered on the teaching of it, had by no means assumed its present importance. It is a significant fact that the class, as he found it, consisted of little more than half-a-dozen students; and no less so that, after ten years' occupancy of the Chair, he left ninety pupils to his successor. Very important in this connection was the publication in 1829, of his "Treatise on Poisons," which was received at the time by physicians, jurists, and men of science generally, as the most philosophical exposition of the subject that had ever appeared, and is even now regarded as a work of great value. From his position as Professor of Medical Jurisprudence, Dr. Christison was naturally called upon to act as an expert in criminal trials; and it was not long before his appearances in that capacity secured for him the reputation of a highly-important witness. First engaged on the trial of Burke and Hare, he has since appeared in numerous *causes celebres*, both in England and Scotland, more especially such as involved the charge of poisoning; while in civil actions raising chemical questions, his services have also been in great request. As a witness, he was remarkable for a lucid precision of statement, which left no shadow of doubt in the mind of court, counsel, or jury as to his views, as was notably illustrated in the Palmer trial.

In exchanging the Chair of Medical Jurisprudence for that of *Materia Medica*, Dr. Christison was confirmed in that line of chemical research for which he had all along shown special predilection. The well known case of the Calabar bean, in which an experiment on his own person was only prevented from proving fatal by timely swallowing of his shaving water was a significant indication of the thorough-going spirit in which all his researches were pursued. Besides the treatise on Poisons to which reference has been made, he wrote the article "Poison" for the seventh edition of the "Encyclopædia Britannica," and the article "Orfila" for the eighth edition; not to speak of numerous papers, elsewhere published, on poisoning with arsenic, opium, and other drugs. As a *pharmacien*, he rendered valuable service in connection with the last edition of the "Edinburgh Pharmacopœia," merged since 1864, like those of London and Dublin, in the "Pharmacopœia Britannica," prepared under the auspices of the General Medical Council; and in his "Dispensatory," published in 1842, he presented a commentary on the then existing Pharmacopœias, characterized, like his book on Poisons, by precision in details, and

by the concise, yet happy expression of suggestive generalisations. Among other results of his experience, he gave to the world in 1838 a work on "Granular Degeneration of the Kidneys," which is still regarded as the leading authority on that subject. Another form of disease to which he devoted special attention was that of fever, in its numerous and perplexing varieties.

In the professorial chair, Dr. Christison proved a singularly lucid and instructive lecturer. As a member of the *Senatus Academicus*, and Assessor for that body in the University Court—an office to which he was elected five times in succession—Professor Christison took an active and prominent part in the management of College affairs. Among the questions agitated of late years, in regard to which he vigorously asserted himself, was that of the medical education of women. In him Miss Jex-Blake and her much-enduring sisterhood found an unflinching opponent, who, in University Court and Infirmary Corporation, lost no opportunity of resisting what he regarded as questionable innovations.

An ardent lover of all manly exercises, Dr. Christison was himself noted, in his youth, as the most accomplished athlete in the University. He handled the gloves with remarkable dexterity, was fond of quiting, showed astonishing endurance as a walker, and could run, even uphill, with the nimbleness of a mountain deer. A story is told of his having, on one occasion, accomplished the rarely equalled feat of running from the College gate to the top of Arthur Seat within twenty-five minutes. In after years, athleticism would often form part of the diversions with which the Professor and his friends relieved the cares of professional life. A favourite haunt with the brotherhood was Mr. Syme's house at Millbank; and, in the course of high jinks on the lawn there, Dr. Christison might be seen pitted to run 100 yards, with another man on his back, against Dr. MacLagan, doing double the distance unencumbered, and winning, too, by an inch and a-half in such apparently hopeless a contest. Even as an octogenarian, the vivacious Professor continued to be remarked for the almost jaunty elasticity of his step; and four years have hardly elapsed since, in pursuance of experiments as to the sustaining virtues of the coca leaf, he walked twice to the top of Ben Vorlich.

In 1857, Dr. Christison was nominated by the Crown to represent the profession in Scotland at the General Medical Council. His seat at that Board he retained till 1873. After having for many years held the honorary office of a Physician in Ordinary to the Queen for Scotland in 1871, he was created a baronet of the United Kingdom, a distinction which was conferred on the recommendation of the then Prime Minister, Mr. Gladstone. Sir R. Christison was in politics a Tory of the Tories. Dogmatic and positive in his opinions, he was inclined to lay down the law in a way that might not always be quite agreeable. To absolute strangers, and more especially to people who might assume, in however slight a degree, the air of patronising the University or the medical profession, his manner was apt to be cold and distant. Such indeed, to a certain extent, was his general bearing towards those he was not in some way or other associated with. On the other hand, friends who had the good fortune to know him intimately found in his nature a fund of geniality such as the casual observer could never have dreamt of. Warmth of heart, and simple, unaffected kindness would seem to have been distinguishing qualities of his private and social demeanour. But no less marked, in private as well as in public, was the contempt with which he treated whatever struck him as paltry or dishonourable. Anything that jarred upon gentlemanly feeling excited in him a repugnance he was by no means slow to express. Thoroughly self-reliant, and conscious at once of his own ability and his loyalty to the profession, he was entirely free from any shade of jealousy in regard to the success of other men; and closely as he identified himself with the University, he was always ready to show sympathy with professional brethren outside, if only he were satisfied that they were doing their work conscientiously and well.

Sir Robert Christison was married in 1827 to Henrietta Sophia, daughter of Mr. David Brown, of Greenknowe, Stirlingshire. Mrs. Christison died in 1849; but there survive three sons, of whom Alexander, the eldest, born in 1828, who inherits the title, was educated at the Edinburgh Academy and High School, and after serving in various capacities, is now Deputy Surgeon-General of the Bengal Army; the second, David, born 1830, has also followed the medical profession; and the youngest, John, born 1832, is a Writer to the Signet, and Secretary to the Edinburgh University Court.

NOTICES TO CORRESPONDENTS.

AGRIOLA asks for information as to the expenses attending the management of, and mode of conducting, cottage hospitals. Can any of our readers comply with the request?

M. J. D.—It is against our rules to prescribe in these columns. In your case, especially, it would be impossible, as the swelling may proceed from a variety of causes, unascertainable except by personal examination.

DR. BUCHANAN.—We hope to find room for the correspondence in our next.

SMOKE AND FOG EXHIBITION.—The concluding portion of our reports on this Exhibition is unavoidably held over for want of space.

MR. SHOTTON will find an admirable description of the syphilitic liver in Dr. H. Thompson's "Clinical Lectures and Commentaries," published through Messrs. J. & A. Churchill in 1880, pp. 117 *et seq.*

W. A. B.—The question is rather one to be decided by a legal authority. As a registered medical practitioner, you have the right of suing for payment of the account in a county court, but if a more private arrangement is possible you will be wise to effect it.

MR. EDGEBATH.—(1) "Nature's Hygiene," by Mr. C. T. Kingzett. (2) Through any publisher or bookseller. (3) Any duly qualified and registered medical man. (4) Either the "Medical Directory" or the Medical Registrar, the last being the official list.

ARISTARCHUS.—The matter has been discussed times without number, and now, as ever, no satisfactory solution of the problem can be quoted. Doubtless it would well repay labour bestowed upon it, but we must warn you against repeating former errors made in connection with it. No one can successfully investigate the question who is not both a careful observer and a skilled comparative anatomist. We shall be very glad to see the result of your inquiry if you elect to pursue it.

DR. DONALDSON.—The licence should be granted in accordance with certain specified conditions, the chief of which is that an expert committee recommends it to be issued to the candidate. In recent cases the advice of this committee has not been invariably followed. Your best plan, assuming that the question of expense does not influence you, is to prosecute the inquiry abroad, where ample facilities abound.

R. E. B.—Your teacher's advice is most excellent; you will be most unwise to reject it.

MR. WISEMAN.—The volumes are four in number, and the price of each is half-a-guinea. They may be obtained separately. The first is that which contains the papers on *materia medica*.

CURIOSITAS.—There is such a book, but we cannot recommend it.

PUBERTY.—The age is no exact one; it varies with the nationality and with the temperament. In warmer countries it occurs at an earlier date than in colder climes.

MR. W. B.—Thanks; scraps of interesting news are always acceptable.

L.R.C.S.—Thanks for drawing our attention to the article, which we had not previously seen; we shall not fail to make use of the information when the proper time arrives.

THE SUPERANNUATION DEPUTATION.—The names of Dr. Pollock, Chairman of Council of the Irish Medical Association, and Dr. Tagert, were inadvertently omitted from the list of those present at the recent deputation to the Chief Secretary for Ireland reported by us last week.

EDITOR OF THE "CHEMISTS' JOURNAL."—Regret we cannot further increase our Exchange List; it is already too large.

DR. J. H. A.—Write to the Secretary for a copy of the "Rules and Regulations" relating to the post.

FEES FROM MEDICAL MEN.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Is it usual for medical men in this town to take fees from medical practitioners? I went to consult a gentleman of standing in Street. He took his fee, which rather surprised me, having always known it to be returned. He was aware that I was a medical man.

Dublin, Jan. 27th, 1882.

Yours, &c.,
L.R.C.S.E.

[It certainly is not usual in Ireland to accept a fee from a medical brother, and we doubt that it is etiquette to offer one. Retired practitioners of independent means might, perhaps, offer a fee, which, under the circumstances, might be accepted; but the cases are very exceptional in which a medical man is paid for advice given to a member of his own profession.—ED.]

THE SUPPLY OF VACCINE LYMPH.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel extremely obliged if you will inform me how, and where, I can obtain some vaccine lymph taken from the heifer direct. I have patients desiring to be vaccinated with it if it is obtainable. Pray excuse this trouble, as I do not know any one else to whom to apply for the information.

Yours very truly,

Loughgal Dispensary, Jan. 28th.

W. W. LEEPER, M.D.

[*.* Our correspondent can obtain fresh calf-lymph on application to Dr. Renner, 228 Marylebone Road, London, W. Terms will be found on reference to our advertisement column.—ED.]

MEETINGS OF THE SOCIETIES.

PHARMACEUTICAL SOCIETY OF LONDON.—This (Wednesday) evening the following papers will be read—"Iodine-yielding Algae: a Proposal for their direct Use in Pharmacy," by James Wheeler.—"Does Cod-liver Oil contain 95 per cent. of Iodine as stated in

Gardol's 'Materia Medica,' by M. Mitchell Bird, F.C.S.—Mr. G. W. Parker, also, will call attention to an interesting collection which he has made of native medicines, &c., from the interior of the island of Madagascar, and Mr. J. G. Baker, of the Royal Gardens, Kew, who has recently been engaged in working out the flora of Madagascar, is expected to be present.

HARVEIAN SOCIETY.—Thursday, Feb. 2nd, at 8.30 p.m., Mr. Osman Vincent, "On Cases of Contraction of the Knee and other Joints,"—Dr. Day, "On Headaches in Children."

ABERNETHIAN SOCIETY (St. Bartholomew's Hospital).—Thursday, Feb. 2nd at 8 p.m., Dr. Percy Kidd will introduce the Medical Discussion on Hemoptysis.

ROYAL INSTITUTION.—Friday, Feb. 3rd, at 8 p.m., Professor Tyndall "On the Action of Molecules, Free and Constrained, on Radian Heat."

ROYAL INSTITUTION.—Monday, Feb. 6th, at 5 p.m., General Monthly Meeting.

ROYAL INSTITUTION.—Tuesday, Feb. 7th, at 3 p.m., Prof. John G. McKendrick, "On the Mechanism of the Senses."

Vacancies.

Belmullet Union, Binghamstown Dispensary.—Medical Officer. Salary, £100, and £10 as Medical Officer of Health. Election, Feb. 2.

Bridport.—Medical Officer of Health for the Borough of Bridport. Salary, £40 per annum. Applications to the Town Clerk not later than Feb. 4.

Bristol General Hospital.—Physician's Assistant. Salary, £50, with board. Applications to be addressed to the Secretary on or before Feb. 18.

General Hospital and Dispensary for Sick Children, Manchester.—Physician. Salary, £300 per annum. Applications to be addressed to the Chairman of the Medical Board on or before Feb. 8.

Glennamaddy Union, Williamstown Dispensary.—Medical Officer. Salary, £120, and £25 as Medical Officer of Health. Election, Feb. 17.

Liverpool Eye and Ear Infirmary.—House Surgeon. Salary, £80, with board. Application to the Hon. Sec. not later than Feb. 10.

Rotherham Hospital.—Resident House Surgeon. Salary, £100, with board. Applications must be sent to the Hon. Sec. on or before Feb. 28.

St. Bartholomew's Hospital, Chatham.—Assistant House Surgeon. Salary, £80, with board. Endorsed applications to the Clerk to the Trustees at the Hospital.

St. Mark's Ophthalmic Hospital, Dublin.—House Surgeon. Salary, 50 guineas, with partial board. Applications to the Registrar before Feb. 18. (See Advt.)

Appointments.

JACKSON, THOMAS, L.R.C.S.E., Assistant Medical Officer to the County Lunatic Asylum, Snenont, Nottingham.

KENNA, DENIS P., L.R.C.S.I., Demonstrator of Anatomy at the Ledwich School of Medicine, Peter Street, Dublin.

LOUGH, J. J., M.B. &c., Medical Officer to the City and East London Dispensary.

LOUGHER, R., L.R.C.P.Ed., L.F.P.S.Glas., Medical Officer for the Roath District of the Cardiff Union.

MORRIS, W. W., M.B., L.R.C.P.Lond., Medical Officer to the Eastern District of the Bingham Union.

SYMES, E. W., M.D. Edin., M.R.C.S., Surgeon to the Halifax Infirmary and Dispensary.

TREHARNE, J. L., M.R.C.S., Medical Officer for the Spotlands District of the Cardiff Union.

LENTAIGNE, J., Assistant Surgeon to the Richmond Hospital, Dublin.

Births.

FINNY.—Jan. 27, at 19 Lower Baggot Street, Dublin, the wife of J. Magee Finny, of a daughter.

Marriages.

FRANKLYN—HALL.—Jan. 28, at Millbrook Parish Church, Edward J. Franklyn, M.D., Deputy Surgeon-General, Army Med. Department, to Matilda, second daughter of the late Colonel Hall, Grenadier Guards.

Deaths.

CHRISTISON.—Jan. 27, at 40 Moray Place, Edinburgh, Sir Robert Christison, Bart., M.D., D.C.S., Physician-in-Ordinary to Her Majesty in Scotland, in his 85th year.

JEFFERY.—Jan. 19, at Pierpoint Street, Worcester, of bronchitis, John Dacie Jeffery, surgeon, aged 71.

MACILWAIN.—Jan. 22, at his residence, Matching, Harlow, Essex, George Macilwain, F.R.C.S., aged 85.

NICHOLL.—Jan. 18, at Wisbeach, David Charles Nicholl, M.R.C.S., aged 35.

OWEN.—Jan. 26, at 90 Lockyer Street, Plymouth, Thomas E. Owen, M.R.C.S. Eng., L.M. Dub., aged 46.

STARR.—Jan. 20, at Richmond, Surrey, Thomas Henry Starr, M.D. Ed., in his 72nd year.

SUTCLIFFE.—Jan. 12 (at the residence of his brother-in-law), John Sutcliffe, L.R.C.P.Lond., M.R.C.S., &c., of Deunark Hill, S.E., aged 33.

THORP.—Jan. 20, at Maldon, John Thorp, M.R.C.S., aged 79.

TOOGOOD.—Jan. 17, at Ashbourne, William Toogood, F.R.C.S.L., aged 62.

TWIGG.—Jan. 17, at his residence, near Clogher, co. Tyrone, Richard Stuart Twigg, M.D., F.R.C.S.I., in his 86th year.

WAUGH.—Jan. 20, at Stewartstown, Thomas Waugh, M.D., aged 65.

RECENT RESEARCHES INTO THE THEORY OF THE LIVING CONTAGIUM, AND THEIR APPLICATION TO THE PREVENTION OF CERTAIN DISEASES IN ANIMALS. (a)

By J. L. W. THUDICHUM, M.D., F.R.C.P., Lond., &c.
(Concluded from page 89.)

CHOLERA OF FOWLS.—There is a disease of fowls, called in France "cholera of chickens," from which many die, when once it has got access to a fowl-yard. The animals affected become torpid, are entranced with somnolence, and die without moving from the spot, the head, as in sleep, under the wing. This disease, too, is caused by a microscopic organism, first suspected by Moritz, a veterinarian of Upper Alsatia, figured by Peroncito, a veterinarian of Turin, and cultivated by Toussaint, a veterinarian of Toulouse, in the manner in which Koch had cultivated the bacterium of splenic fever and with the same success. This organism was now studied by Pasteur, and he found that while it thrived well in chicken broth neutralised by soda, it refused to live in decoctions of yeast such as would support the splenic fever bacteria, and enable them to multiply. The chicken cholera microbion killed chickens rapidly after inoculation; it did not kill guinea-pigs, but merely made them ill for a time, by producing a small abscess. The contents of the abscess always contained the microbion, which, when re-inoculated to chickens, killed them rapidly. Chickens which merely ate some of the pus from the abscess of the guinea-pig, died rapidly, and the fæces which they voided during the short sickness swarmed with the microbia. The microbia were easily destroyed by a little diluted sulphuric acid, but they retained all their virulence after cultivation in neutralised chicken broth; and this virulence was so great, that if the point of a needle was dipped into a cultivation solution in which the microbion was growing, and was then

plunged into the tissue of a fowl, the latter died—mostly in twenty-four hours. Of twenty fowls thus treated, all twenty died in two or three days—most commonly in fifty-four hours. Pasteur now found that by certain changes in the mode of cultivation of these microbia (changes which will be alluded to lower down), the infecting energy, or as we perhaps better express it, the metabolic virulence, could be greatly diminished. The modified microbion would make twenty chickens specifically ill, but kill only few or none. And these twenty or eighteen chickens, after recovery from the modified disease, would be protected from the influence of a renewed introduction of the same contagium, as well as of the first always fatal form of the disease. Pasteur had, therefore, repeated upon fowls the old experience of protection by inoculation with a modified specific contagium. Inoculation with small-pox was based upon the recognition of the existence of such modified, or mild small-pox. Cow-pox, which was supposed to be a contagious disease peculiar to the cow, and to act vicariously, in protecting men from small-pox, was supposed by some to be modified small-pox only. And this view was sufficiently strong with some—as with Badcock, of Brighton, Ceely, of Aylesbury, and Green, of Birmingham—to induce them to inoculate cows with small-pox, and to use the (modified) contagion thus produced for the protective inoculation of men, commonly termed vaccination. Much of the so-called "vaccine" lymph now used in England is actually small-pox lymph modified by one passage through the heifer, and many passages through human beings. But in the case of small-pox and vaccine, it has not yet been shown that the virus is a living being, whereas in the case of the virus of the fowl-cholera, the "mitification," if I may be allowed the term, was effected after the living nature of the contagium had been ascertained.

When the microbion in its virulent state is inoculated in the great pectoral muscle (the breast of the fowl), it multiplies there, and destroys much muscular tissue. But at last it becomes confined in a cavity with pus, and with the piece of muscle destroyed, continues in it as a sequestrum. Here the general disease ends; but the

(a) Read before the Chemical and Physics Section of the Society of Arts, Jan. 26, 1882.

microbion remains living and capable of propagation in new individuals. The abscess may be emptied out and will heal with the necessary contraction by loss of substance. Now the pectoral muscle is protected from the effects of any similar inoculation; it has acquired a special immunity, in which, if I understand M. Pasteur right, the rest of the body of the fowl does not share. The immunity of the entire fowl is only obtained by protective inoculation with the modified, not with the original, so to say, wild poison. Pasteur supposes that this immunity of the muscle was, in fact, an incapacity to nourish the microbion, caused by the suppression (or removal in the shape of pabulum) of some principle or matter which life does not restore, and without which the microbion cannot be developed. This local immunity is part of the question of the immunity of entire organisms. From this immunity, says Mr. Simon, the inference seems unavoidable, that each contagium operates with a chemical distinctiveness of elective affinity on some special ingredient or ingredients of the body; and that exhausting this particular material in febrile process, which necessarily ends when the exhaustion is complete, is the bodily change which the contagium specifically performs.

However that may be, it is certain that, at this point, the investigation of the effects of living contagia must be taken up by the pathological chemist. For the phenomena indicate various chemical changes, not only of parts of the body, but also of matter emanating probably from the microbia themselves. For when, e.g., the microbia of the fowl cholera are cultivated in a proper previously sterilised solution, and when this solution is now filtered so as not to contain any microbia, and when this solution, free from microbia, and which cannot therefore produce any disease like fowl cholera by inoculation, is injected into the subcutaneous tissue of a fowl, the animal shows some nervous disorder, and some yawning-like motion of the beak; it then becomes somnolent as in the fowl cholera itself, but after about four hours recovers as from a dose of narcotic poison. The microbion, therefore, produces a narcotic poison during its life, which acts upon the nervous centres. The disease, as a whole, consists therefore of lesions of different orders; one caused by the microbion, its obstruction of lymph—and blood—vessels, its abstraction of oxygen from the blood—corpuscles and other effects; the other order being chemical effects of a truly poisonous kind, caused by substances new to the economy, and excreted by the microbion, or left as residues of decomposition which it engenders.

But I must not discuss at too great length a disease which has probably little practical importance in this country. The fowl-yard has its diseases, and diphtheria is one of them. Young pigeons die frequently of the same disease. It would be well if all could be protected or cured. We, for our part, must pass to perhaps the greatest result of Pasteur's studies, namely, the protection of cattle—oxen, cows, and sheep—by protective inoculation, with a modified bacterium of splenic fever or anthrax, against the true and hitherto frequently fatal disease, splenic fever. Chauveau, of Lyons, while experimenting with splenic fever contagium on sheep, which he had bought in the open market at Lyons, had found that nine sheep in succession were proof against it. On inquiry, he learned that these sheep had been imported from Algiers. He then imported seven sheep from Algiers directly (Constantine), and inoculated them with splenic fever contagium of a virulent kind. A test-sheep, from Dauphinée, was also inoculated. The latter died within three days, while the seven Africans showed no splenic fever symptom, except a slightly raised temperature. Five of the Algerian sheep were inoculated twice more, with test animals by the side of them; amongst the latter being Tuscan sheep and lambs, Piedmontese sheep, and a rabbit. All the latter died, while the Africans exhibited a perfect immunity. Chauveau now went to Algiers, and experimented further;

out of 47 sheep inoculated, only 8 took the disease and died; 39 resisted to all repeated inoculation. Thus it was proved, for the first time, that any sheep could resist the splenic fever poison, which, with European sheep, had been always fatal.

THE CONTAGIUM OF SPLENIC FEVER.—Pasteur now investigated, with the aid of the French Government, the manner in which animals might become infected with splenic fever. When sheep were made to eat clover (*lucerne*), on which bacteria, reared from splenic fever contagium, had been poured, several died, but after a period of incubation, extending sometimes to eight and ten days, while the greater number escaped infection. It was, therefore, probable that many of the infections occurring in France, and which amount to three per cent. of all the flocks annually, were caused by bacteria, accidentally on the ground and on food, and swallowed by the animals with their food while pasturing. This surmise was proved, experimentally, to be probable. When animals, dead from splenic fever, were buried in arable or pasture-land, and healthy animals were allowed to pasture over the graves, the latter became infected with splenic fever. It was now shown that, when the splenic fever contagium is in the filiform stage, it perishes with the putrefying body, as it cannot live without air; but when it is in the stage of spores, or germ-corpuscles, it is not affected by the want of air, and survives. Such spores are found in and above the burying-places of animals dead from splenic fever ten and fourteen months after burial, and are capable of causing the disease in new animals. Even above animals buried two metres deep, these spores were present two years later. These germs are carried to the surface by earth worms, in whose interior they are also found. The little cylinders of earth, deposited by worms as faeces, contain the germs of the splenic fever contagium; and the rain, when disintegrating these little heaps of cylinders, spreads the germs about, causes them to adhere to adjacent vegetables, and to be carried into water courses or ditches.

Pasteur now proposed prophylactic burial of all animals which might die from splenic fever, and believes that with these measures alone the disease could be stamped out in a few years. (It had been stamped out on German farms in Saxony, an experience which is related in a letter from the Saxon Minister to the French Court in 1865.) Meanwhile, Toussaint made experiments concerning the inoculation of cattle with a mild splenic fever contagium, for the purpose of protecting them in the same manner as men are protected from virulent small-pox by inoculation with a mild form. These experiments succeeded partially; some animals died, but the survivors, which were the great majority, were protected from the effects of renewed inoculation. Similar experiments were successfully made in this country by Greenfield, now of Edinburgh. On the whole, it was again found by test experiments that cows are much stronger in resisting splenic fever than sheep. Of twenty cows which were inoculated with splenic fever in 1850 to 1852 by the Association Médicale de Chartres, only one died, while of forty-seven sheep inoculated by the same Association, thirty-five died and twelve survived. While, therefore, the cow does naturally frequently fall ill with splenic fever it does not always die, or rather rarely dies, while sheep die in the great majority of instances in which they become infected, Barbary sheep always excepted.

Pasteur now studied further the mode of attenuating, as he termed it, the contagium of fowl cholera. He had observed the first attenuated virus when he took some from a fowl which had indeed died from the cholera, not, however, from the acute, but from the chronic form, and had cultivated it for weeks and months in successively renewed solution. At first it lost nothing of its virulence; but when the cultivation was renewed uninterruptedly during from six to eight months, but at longer intervals between the sowings, the fatality of the disease, following inoculation with this cultivated contagium,

diminished or disappeared. A contagium was produced, which caused a mild, non-fatal disease, and the animal which had undergone this process was protected from the effect of the most virulent contagium, as has already been stated above. What is of importance now, is the cause of the attenuation. Pasteur surmised the oxygen of the air to be the principal cause of it. If the virus is cultivated in hermetically sealed tubes, with only a limited amount of air, no attenuation takes place, and a tube, thus charged, and kept for as many as ten months, retains the contagium in all its original virulence. This feature he believed to be a principle to which other contagia might show obedience. This was found to be the fact for the splenic fever contagion. Cultivated in the presence of air, and re-sown at long intervals (the intervals are not accurately stated, and differ from different cultivation, particularly when they are already somewhat attenuated, while others, of virulent strength, may have their sowing deferred much longer), the bacterium changed its character; it became incapable of causing death in the most susceptible of animals, but retained the power of producing some slight febrile disorder, after the disappearance of which the animal was inaccessible to the most virulent form of the contagium. It was as proof against splenic fever as a vaccinated person is against small-pox. The experience was now raised to a method of protecting herds from splenic fever. Test experiments were made at the public expense, and under responsible inspection and control. Pasteur having predicted the results to the Commission, which had made a record of the prediction, was fully borne out by the results which the Commissioner had to verify. All non-protected animals which had been inoculated with active virus were dead; all animals previously protected by inoculation with modified virus, and now tested with active virus, were living and well. Since that time, many thousands of French animals have been inoculated with the modified virus, with the view of protecting them from spontaneous splenic fever, i.e., splenic fever which they might accidentally contract where the germs of it occur.

Many are the diseases which are ascribed to, or are actually proved to be caused by, bacteria, similar to, though mostly much smaller, than those of splenic fever. One of the best known is pig-typhoid, so ably elucidated by Dr. Klein. Lately, a new one has been discovered, by Dr. Ballard, probably also originating in the pig, and affecting men who consume the pork—even when cooked.

But I must hurry to conclude this very imperfect account of one of the most important subjects of modern science. There are not wanting objectors to the protective inoculation of animals, as there are those to vaccination. They will do good by opposition if it be founded upon truth and experiment, particularly on animals. Probably the stamping out of this and kindred diseases by isolation of cases and germs might be preferable to general inoculation. But antidotes—true medicines—are wanted for most of the virulent diseases, and it is in their discovery that the chemical method of investigating disease will, in future, meet with its greatest successes.

A SHORT RETROSPECT OF THE SANITATION OF FORMER YEARS AS CONTRASTED WITH THAT OF THE PRESENT DAY. (a)

By FRANK J. DAVYS, B.A., F.R.C.S.L., &c.,
Coroner co. Dublin, Swords.

(Concluded from page 93.)

I HAVE particularly referred to the period three years preceding 1866, as it was in 1863 my duties as medical officer in Swords commenced. As the town of Swords, I may here observe, was burnt seven times by the Danes, the houses were afterwards rudely and hurriedly built,

(a) Read before the Association of Medical Officers of Health in Royal College of Surgeons, Ireland.

and when it sent two members to Parliament, each cottager was considered a voter, and hence it was that so many mud-wall houses, without even back doors, rose as if from the earth, and consequently sanitary laws were never dreamt of. In the lapse of years these mud-wall cottages crumbled away, and have been replaced by several well-built houses, but many of the cottages of the poor consist of only one apartment, and none of more than two. They are wanting in everything that should constitute them deserving of a home for a Christian family. Six months ago in this metropolitan county, a few miles from Swords, a family consisting of five (the father, his wife, and three children grown up), lived in a small cottage which had but one apartment; that was their kitchen, bed-room, dressing-room, &c. A young man, of the labourer class, got married to this man's daughter, and there bride and bridegroom located themselves, till informed, by my directions, by the sanitary officer that I reported that the house was overcrowded, and prejudicial to the health of its occupants, and accordingly the bridal party took their departure to other quarters. Here the Public Health Act was of service. In thus speaking of how degrading it must be, whether we look at it morally, socially, or otherwise, to have human beings huddled together in cabins, I am induced to quote the words of a distinguished writer on this subject, viz., "Modesty must be an unknown virtue, decency an unimaginable thing, where in one small chamber, with beds lying as thickly as they can be packed, father, mother, young men, lads, growing and grown up girls, two, and sometimes three, generations, are herded together; where every operation of the toilet and of Nature, dressings, undressings, births, and deaths, are performed by each within the sight and hearing of all; where children of both sexes to as high an age as twelve or fourteen or more, occupy the same bed."

The above is a true picture of the state of things that exists in many of the cabins of the poor in rural districts in Ireland. The houses—many of them—are badly built, with damp floors and sweating walls, and if supplied with a back room, the liquid filth from the yard is carried by a small sewer through the kitchen of the house, and within an inch or two of the surface, to the open channel in the public street. The roofs of the houses are generally covered with a rotten thatch, a form of house covering which I hope may yet disappear. The walls are often in a half-tumble down state, and in these miserable hovels the sick, as well as those in health, lie down together, and when death comes the living and the dead occupy, during the days and nights of the waking, the one apartment, and that one generally overcrowded. I am pretty certain there is not a public health officer in Ireland—by which I mean a Poor-law medical officer—but finds himself in a position to state that since the Sanitary Act of 1866, and since the passing of the recent Public Health Act, that preventable diseases have decreased in their respective districts (at least in those districts in which proper sanitation had been attended to), to the extent in numerous instances of 60 per cent. Dr. Kelly, of Drogheda, in a report published by him in the *Medical Press and Circular* of last January twelve months, set forth the great diminution of disease in his district since the passing of the above Acts, assigning at the same time full credit for these satisfactory results to the proper enforcement of sanitary measures. I may add that in my own district the falling off in the number of cases of preventable diseases is fully in excess of 60 per cent., owing to compulsory sanitation. Whilst I speak so favourably on the wisdom of the Legislature in having passed such sanitary laws, I do not mean to convey the idea that the manner in which these laws are framed is perfect. There is far too much red tapeism surrounding their proceedings. For instance, if a nuisance, no matter how pernicious it may be, requires immediate removal or abatement, the party on whose premises the nuisance exists need not take any steps in modifying or interfering with it till he receives the mandatory order from the exe-

cutive sanitary officer. In this order is embodied the recommendation pronounced by the public health officer in reference to the nuisance. The recommendation is the result of his having inspected the place where the nuisance exists, and then reporting same to the sanitary authority, the board of guardians. This latter board meets on an average once a week in rural districts, or rather they are supposed to meet once a week. The public health officer's report in reference to the glaring nuisance lies over till the following week if the board, as it often happens, does not meet the week the report is sent in. In the meantime the nuisance is in full swing, the party responsible for its removal, not receiving the legal notice to do so, takes no heed of it. Very often it is customary for boards of guardians, before directing their executive sanitary officer to issue the notice for removal of the nuisance, to order him to send the public health officer's report to the dispensary committee, to have them sit in judgment on it, because the nuisance complained of may require to be inspected by members of the committee, who could further advise as to the best mode by which to deal with it. This may appear very prudent of the board of guardians, but they should recollect it is, I might say, an illegal procedure on their part. They constitute the sanitary board, and they have no authority to delegate to any other committee or board their functions. Obviously, their doing so would, even if legal, be a further procrastination in the removal of the nuisance described in the report of the medical officer of health.

I am aware that, as a rule, Poor-law medical officers in Ireland (*ex officio* public health officers) complain bitterly of the disagreeable duties imposed on them by the Public Health Act, and that they find it very difficult, in a conscientious exercise of their functions, to avoid taking cognizance of nuisances existing on the premises of their patients. I would make two suggestions on these points—first, to avoid delay in the red-tapeism in order to have a nuisance abated or removed before the order for such would be forwarded through the executive sanitary officer. This officer, it will be recollected, cannot issue his order till he first receives the recommendation or actual purport of that order from the public health officer, and the latter sends it after his inspection of the premises. To avoid delay, I would suggest that the law should empower the public health officer, after his inspection of the premises on which the nuisance exists, to send at once to the owner a suggestion, such as he sent to the board of guardians, stating that a copy of same will be laid by the sanitary officer before the board of guardians, who will institute proceedings if necessary. The sanitary officer could lay a copy of the order given to him to serve on the owner of the premises before the board of guardians, and thus the public health officer might be saved the trouble of writing out his recommendations in duplicate. No. 2 suggestion,—as to the means by which to overcome the apparent difficulty of offending patients whose premises you have to report as pregnant with nuisances prejudicial to public health. In such cases, and in every case, I would have the sanitary officer to report such to the public health officer, and, with that document in your hand, your attention being directed to it by the sanitary officer, no sensible man could find fault with you for doing your duty. If he removed or abated the nuisance within a given time I should have said in suggestion No. 1, I would not report him to the board of guardians—in other words, the sanitary board. It might be said the sanitary officer might not be aware of the existence of a nuisance in those places, but there is nothing to prevent his calling there and judging for himself. It would be necessary he should do so in all cases, as I would have him as the witness in any prosecutions by the sanitary board. He might have to prove that he saw the nuisance as set forth in the public health officer's report, that the document produced was the report referred to, and that the nuisance was still unabated. I believe if this, or some such plan, were adopted in the rural districts, obviously less delay would occur in the

removal of nuisances, and I consider that under this arrangement of having the sanitary officer to report to the public health officer in all cases, there could not be any bad feeling entertained towards the doctor, as his inspection followed the report to him of the sanitary officer. But, notwithstanding any delay or imperfection in the Public Health Act, it is really a matter of great congratulation that immense sanitary improvements have been achieved; no longer are pigs and donkeys, and every kind of quadruped allowed to lay claim to a comfortable portion of the dwelling-house of man, no longer will the sickly mother or the nervous child be disturbed at night by the gruntings of the pig, and no longer will they be awake at early dawn by the loud braying of the donkey; no longer are filth and sinks allowed to accumulate at the very door-steps; and no longer will the fever-stricken inmates be allowed to occupy the same bed with healthy human beings. The 141 sect. of the Public Health Act can enforce their removal, but in carrying out the law in this respect a difficulty, I am sure, must arise. Who is to take the fever or small-pox (as the case may be) patient from the bed and put him into the fever-van? the relatives, already annoyed by his removal, will not lend a hand, the police will not approach the bed in which the patient lies, the driver of the van must mind his horse and won't give assistance, I would suggest that two strong nurses from the hospital should, in such instances, always accompany the fever van for that purpose. Each year, as we advance, the people are becoming gradually aware that compulsory sanitation must tend to the preservation of their own health. Although it is hard to convince them of the value of preventive measures, whilst any advertisement from the most deliberate quack setting forth a cure for all diseases immediately arrests their attention and opens their purse-strings, and to this may fairly be attributed the resources of quackery in this country. In small towns and villages in Ireland cottagers have difficulty in cleansing out their yards, as they have no place to which to remove the compost; this entails much inconvenience, especially in seasons of the year when farmers do not require to purchase manure for their lands. I consider that sanitary authorities should provide a space outside each village, remote from a house or well, to which manure and contents of ashpits should be periodically removed by a sanitary cart; the amount of money that the total mass of compost would realise would more than compensate them for the expense incurred in its removal. A farm-manure depôt could be thus easily established. It is not unusual for public health officers to complain of the apathy manifested by boards of guardians in carrying out their suggestions in removing or abating nuisances. It is my experience that the sanitary board such as Balrothery Union, when any practical suggestion is laid before it for the improvement of the sanitation of the district, or any part thereof, that the board freely enters into the matter, and if the improvements do not involve an immediate and serious increase in taxation, they either carry out the plans, or do so by instalments. In thus using the word "plans," it reminds me now—as it has often occurred to me before—to remark that a public health officer should be permitted, when necessary, to consult the county engineer. It could not be expected that a doctor would be thoroughly versed in all the details necessary in taking levels, &c., in the construction of sewers, &c., when recommending such to the sanitary board. Though I am aware that both the 36th and 17th sections of the Public Health Act deal with the sale of sewage by contract for any extensive utilisation of same, there is not in any rural district in Ireland that I am aware of, any organised system for the removal, periodical or otherwise, of compost by the sanitary authorities. But time would not at all permit me to go into any extensive details as I would desire, as to the various means I would suggest for improving still further the sanitary condition of rural districts in Ireland. This much, I may remark that I have given some proofs and mentioned some facts that would go to show that the peasantry of Ireland have been under-

going a form of moral and social decadence; in support of this argument, as well as of the comparative physical degeneracy of the Irish peasant, I dwelt on at length in a public lecture delivered by me in Dublin last December, in which I fully discussed the habits and mode of living of the rising and present generation as contrasted with those of half a century ago. The many who honoured me with their presence on that occasion considered I had fully proven the argument. I showed that it could not now, perhaps, be said of the Irishman, when submitted to the test as referred to by Sir Robert Kane in his "Industrial Resources of Ireland" in which he mentions "that, from a comparison of the Irishman in height, weight in pounds, and average strength in pounds with the Scotch, English, and Belgian, it was proved that (at that time) 'the Irishman was the tallest, the strongest, and heaviest of the four races.'" But the muscles and bones of children in those days were allowed to grow, they were not stunted and strained by being put to heavy manual labour at an early age. Little boys were not to be found lolling round public-houses chewing or smoking tobacco; their diet was not from almost their infancy strong infusion of tea, but good milk with oatmeal porridge. In thus alluding to the diet of the labourer of the present day and to my previous remarks on the comparative immunity from typhoid fever enjoyed by the peasantry, I cannot help remarking that either of two things must be deducible in reference to what we would term impure drinking water as a typhoid fever factor—viz., either that it is *not* the great potent agent in developing typhoid fever, or that its danger in that respect is rendered innocuous by first boiling the water before drinking it. From time to time I made it my special study, or duty, to watch the effects of persons using, for all household purposes, in making tea, &c., common ditch water and water from wells or pumps, concerning which I held certificates from Dr. Cameron that the water was highly impregnated with sewage matter and unfit for human use, yet not in any one instance could I trace one case of typhoid fever or diarrhoea to the use of these waters. I found that in nearly all, but not all, the water (which was in the morning put into a big kettle) was generally boiled before being used, so that when not taken in tea it was cold boiled water. Probably the deleterious properties of the water were removed by boiling.

I feel, Sir, I have protracted these observations far beyond the limits that I intended, though omitting many matters which, if the audience that I have the honour of addressing, were not composed of scientific men I would regret not having dwelt on—such as the form or construction of cottages for the rural population, the necessity of submitting plans to the sanitary board, the latter to have, as a member of its board, the county engineer, with many other subjects to which I would wish to refer.

I will now conclude, Sir, by expressing my earnest wishes that I may live to see the day when the poor labourer class of Ireland will be properly housed, when no cause for either drunkenness or any moral depravity will be infused into them by want of decent habitation, that no disgust for their homes or fire-hearths owing to their wretched dwellings will grow up amongst them or distract them from their peaceful avocations, and that there will be vested in the Local Government Board power to construct suitable dwellings for the poor in villages in Ireland, and that coffee houses by which the labourers may be tempted from the baneful influences of public-houses will become general, and that the Factory Act will be extended so as to prevent children under a certain age from being employed at severe manual labour. When these improvements take place, I will have the happiness of knowing that a large section of the community are in the upward scale of progress, and that peace, prosperity, and happiness will reign amongst them.

Clinical Records.

ST. MARY'S HOSPITAL.

A Case of Vicarious Menstruation from the Ear.

Under the care of Mr. FIELD.

A. B., *æt.* 18, single, was admitted August 22, 1881. She stated that when six years old she had a blow behind the right ear; this caused a discharge of yellow matter, which has continued ever since. She has been occasionally subject to "gathered" fingers. When about twelve years old she began to have pains in the back now and again, and became subject to sick headache. When fourteen years old she woke up one night with epistaxis, and this returned the following day, and again three days after. About a month subsequently, bleeding from the right ear came on, which lasted an hour, and was very profuse. This was accompanied by "buzzing in the ear and ticking in the head." Since then she has regularly every three weeks lost blood from the right ear. The hæmorrhage lasts not more than about ten minutes, as the patient always checks it with cold water applications. She has only once menstruated from the vagina; this was in 1879, when, after she had consulted a medical man, who gave her medicine and ordered her to put her feet in mustard and water, a slight flow was produced. Bleeding from the ear was taking place at the same time, for, as she said, "it was the proper period for it."

The patient had a large perforation in the right membrani tympani. She was in the hospital for some months, during which time the hæmorrhage from the ear reappeared regularly every three weeks. Her breasts were small. No os uteri could be felt by finger. There was copious yellow vaginal discharge.

Remarks.—The evidence that this hæmorrhage was vicarious menstruation appears singularly complete. To begin with there is the fact of ear disease, with the establishment of suppuration at six years of age. When twelve years old she became subject to pain in the back and sick headaches. Here we have two factors indicated; a liability to cerebral hyperæmia at the menstruation epoch, and a diseased surface within her tympanum ready to suffer from this periodical turgescence. To the epistaxis at fourteen years, during three days, we have another indication of the cerebral hyperæmia. This, we see, is followed, about a month afterwards, by bleeding from the right ear, since repeated regularly every three weeks. Meanwhile, she has never menstruated, except on one occasion, when the flow was of a somewhat doubtful character, and artificially induced. Vicarious hæmorrhages, such as this, have been known to occur from every mucous membrane in the body. Hinton says of hæmorrhage from the ear: "It is a symptom of suppressed menstruation." Hæmorrhages from the gastro-intestinal, bronchial, vesical, buccal, and nasal mucous membranes, from the conjunctiva, the skin, old ulcers, cicatrices, and nævi, have been frequently recorded. Although so many cases of vicarious hæmorrhages have been recorded, it appears of late years to have become fashionable to hold a wholesome scepticism as to their occurrence. This may be well shown by comparing the scanty attention paid to them by Dr. Bristowe in his standard work on Medicine, in which he barely alludes to them in dealing with the causes of hæmorrhage from the gastro-intestinal mucous membrane of the air-passages. On the other hand, Sir Thomas Watson, in his early editions, mentions them at considerable length. In discussing each form of hæmorrhage he speaks of their frequent occurrence, and gives several cases as examples. That they indicate a most remarkable condition of the vascular system—probably a local turgescence, and a general increase of vascular pressure—occurring at the menstrual epochs cannot be doubted. This has been well shown by two very remarkable cases. One was recorded by Dr. Mason (*a*) of a young lady, *æt.* 15, who had the most extraordinary hæmorrhages from the skin, occurring in various parts of her body. In this case the changes in the skin could be watched; they were instantaneous, the "skin appearing perfectly healthy and whole one second; melted away and bleeding the next." In this case the hæmorrhages, though coincident with an arrest of menstruation, did not

(a) *Edin. Med. Journ.*, September, 1866.

occur at monthly intervals, but much more frequently; and part of the period she was under observation they were daily, but her menstruation also, when it first recurred, was at intervals of only one week. Another remarkable case is recorded by Dr. Puech. (a) In this instance the patient never had any menstrual flux, though she suffered from uterine pains every month. At 17 years of age these were replaced by headaches, and at the same time her physiognomy underwent a marked change, owing to the appearance of varices of the facial and superficial temporal veins and their tributaries. These varices increased gradually, and at certain times attained considerable size, and one of them on the head burst, allowing the escape of a large quantity of blood. These hemorrhages occurred very irregularly, but instead of exhausting, they greatly relieved, the patient. From time to time the conjunctiva of the left side became congested, and once a good deal of blood was lost therefrom. The hemorrhages from the head after some time ceased, and were replaced by frequent epistaxis. Very recently still further light has been thrown upon the vascular condition which produces vicarious hemorrhages by observations made by Miss Elizabeth Jacobi, M.D. This lady has demonstrated by means of the sphygmograph that there is a general rise of arterial pressure occurring during the menstrual epoch. If to this general rise of pressure we add a local turgescence at any weak spot, we have all the factors required for the hemorrhages. Hemorrhage into the middle ear, though of an entirely different nature, and not periodical, occurs occasionally as a result of otitis, and is described by Roosa as "otitis media hæmorrhagica." His were cases of acute aural catarrh, which terminated suddenly with an abundant hæmorrhage through the drum-head. Similar discharges have been caused by Bright's disease, and are analogous to the hæmorrhages into the retina from the same cause.

Special.

THE HEALTH OF THE NAVY. (b)

ACCORDING to the Blue Book just published, the medical statistics of the Royal Navy show the following general results:—The total force in the service afloat, corrected for time, was 44,770. In that force the ratio of admissions on the sick list per 1,000 men for the year was 1172·36; daily sick 44·94. As to loss, that by death was in the ratio of 12·57; by invaliding 31·11; thus making by these causes combined a rate of non-efficiency equal to 43·68 per 1,000 for the period. The ratio of invaliding for disease alone was 29·14; and for casualties 1·96; thus showing that the latter cause has less effect among our men-of-war's men than, considering the nature of their duties, might be expected.

An interesting table given at page 6 shows the comparative sickness, according to age, during the year, and that preceding. Boys and men between fifteen and twenty-five, furnish, as on previous occasions, a sick-rate largely in excess of that observed in the other decennial periods; while the lowest ratios of sickness are, as before, those of men above forty-five. The unfortunate loss of the *Atalanta*, however, has more than doubled the death-rate of the first period, as her crew was composed almost entirely of young men.

The statistics of syphilis show by no means the favourable results that might have been anticipated, considering the operation of the Act in force against venereal diseases. On the home station primary syphilis shows an increase equal to 2·67 per 1,000 as compared with the previous year; on the Mediterranean station an increase of 1·82; North American and West Indian 16·93; (something altogether enormous, and for which no explanation is offered); South-East Coast of America 2·3; Pacific 1·85; China 1·35; Aus-

tralia 41·35—an increase which is absolutely alarming; and yet, on turning to the report having reference to that station, at page 68, not a word appears as to the circumstances to which this increase may be assigned; in the "irregular" force an increase of 10·67. In only two commands is a decrease shown, viz., East Indies, equal to 9·06; Cape of Good Hope and West Africa 1·58.

At page 54 an interesting report occurs of an epidemic of paroxysmal fever on board the *London* at Zanzibar. The first appearance of this form of disease occurred in January; the number of cases increased in February, but became fewer in March. The improvement, however, was only temporary, for in April the disease attacked fifty-four persons of the crew of that vessel. In May the number fell to twenty, and in the next three months only seven cases altogether came under notice. The specific cause of this epidemic on board the *London* was evidently not detected. On shore, with the exception of a few cases in March, the hot season of the year was unusually healthy; and, moreover, the men of the *London* employed in the cruising boats, and exposed to all those conditions which are said to generate and spread malaria, had a most remarkable immunity from it. This is one of several instances recorded in the Blue Book before us in which facts as they occurred have been altogether opposite in their nature to what, according to all principles of theory, they ought to have been.

THE "MEDICAL PRESS AND CIRCULAR" REPORT ON THE SMOKE ABATEMENT EXHIBITION.

No. III.

CLOSE STOVES AND CLOSED FIRE GRATES.—These are not so attractive from a sanitary point of view as open grates, as they lack the redeeming feature of the open fire system, viz., the great assistance to ventilation afforded by the latter. Many of those on view, though, are smoke consumers, and some are also air warmers. Of all it may be said that they are infinitely more economical and cleanly than any open fire.

Messrs. Brown and Green exhibit the "twin" stove, which is smoke consuming, ventilating, and can be made to warm two rooms if desired.

Mr. T. J. Constantine, of Fleet Street, exhibits the patent smoke consuming "treasure" stove. The fire can be partially seen.

Mr. R. W. Crosthwaite, of Upper Thames Street, exhibits Armstead's patent stove, in which, after leaving the stove the smoke is drawn round a cylinder at the top of the stove before escaping up the chimney, thus retaining more heat in the room. This is not a smoke consumer.

Messrs. Doulton and Co., of Lambeth, exhibit their portable radiating tile stoves in various sizes, designs, and colours. These are constructed almost entirely of "Doulton" ware, as little metal as possible being made use of. The flues may be either ascending or descending. They are nearly completely smoke-consuming, and have a tile ventilating shaft, through which fresh warm air streams into the room.

Messrs. Feetham and Co. exhibit an independent smoke-consuming warm air stove (with open fire) for use in halls.

Messrs. J. and F. Farwig, of Queen Street, have a slow combustion coal calorigen, on the same lines as their well-known gas Calorigen. It will burn coal or coke, last many hours without attention, is ventilating, and economical. It can be adapted to the ordinary chimney opening.

Mr. Harry Hunt, of Newington Green, has on view the "Hygiene" hot air anthracite coal stove for warming and ventilating. This somewhat resembles an ordinary fire, as it is set in the ordinary chimney opening, and is closed in front—not by metal—but by talc doors, through which the fire can be seen. The use of anthracite, or other smokeless fuel is essential, as otherwise the talc doors would soon become coated inside with soot. The air passes through a chamber lined with fire-clay. The fire projects well into the

(a) De l'Atresie des Voies Génitales de la Femme. Paris, 1864.

(b) Official Report of the Health of the Navy in 1880.

room. It can be kept alight for months without extinguishing, the ashpan being removed at intervals, and emptied.

Messrs. Musgrave and Co. exhibit their well-known patent ventilating slow-combustion air warmers which will burn coke or coal, and are smoke-consuming.

One stove exhibited need only be mentioned to be condemned. The inventor maintains that he can absorb the smoke produced by a jet of steam, and thus dispense with any flue. The slightest knowledge of chemistry should convince any one that warm water will not hold in solution, even its own bulk of carbonic acid.

Mr. W. White, F.S.A., of Wimpole Street, exhibits the "Shrewsbury Warming Apparatus." It is built in firebrick, and the only iron in contact with the fire is the fire-bar. It is smokeless, and will burn all day without care. Warm air is introduced to the room through an iron case provided with gills.

Messrs. Yates, Haywood, and Co., of Upper Thames Street, exhibit the "Miser," which is said to be extremely economical in the consumption of fuel, and nearly smokeless.

GAS AS A WARMING AGENT.—A very large variety of gas warming apparatus are shown in action. Many of these, unfortunately, are the very reverse of sanitary appliances, as they permit the escape into the room, of the whole of the fumes evolved by the combustion of the gas. The ornamental and cheerful character which many of them present does not compensate for their harmful effects. The same may be said of all the ordinary paraffin stoves, of which some are on view. The latter, although combustion may be so perfect as to give off no smell, evolve carbonic acid of course in the same manner as gas and other carbonaceous fuels, and in quantities varying according to the amount burnt. If the fumes were properly carried away, paraffin would offer several advantages over gas as a heating agent, e.g., if accidentally blown out, explosive gas is not evolved. A good ventilating paraffin stove with flue is still a desideratum, and if brought out should command a ready sale in country districts where gas is unattainable. As yet, Tait's Thermo Ventilator is the only ventilating gas stove which has been adapted to burn either paraffin or gas.

On first entering the Exhibition, one of the most prominent objects is a system of hot-water boilers and pipes heated by gas, the fumes being allowed to escape polluting the atmosphere and yielding an offensive odour. Further description is needless, as it stands self-condemned. The makers suggest its use in bedrooms and nurseries.

Mr. C. R. Stevens, of Lewisham, exhibits a combined steam and hot-air heater, in which two ordinary gas jets are made to convert water into steam, which passes through a coil of pipes. Cold air can be introduced into the room and warmed by contact with the coil. The gas fumes are removed by the flue. The apparatus is constructed to stand in an ordinary chimney opening, is cheerful in appearance, and the inventor claims that an ordinary room can be warmed by two gas jets at a cost of 3d. a day.

Mr. Gillingham, of Chard, the well-known surgical mechanic, exhibits an effective gas-heated hot-water apparatus. After extracting nearly all the heat from the gas fumes they are either removed by a small outlet pipe, or Mr. Gillingham suggests that lime may be used to absorb them, and thus obviate the necessity for a flue. This should certainly be practicable on a small scale.

Several gas-heating stoves are offered for our attention, in which the makers profess that by causing the fumes to circulate through a series of pipes, they "become thoroughly condensed and are carried off in the form of liquid." On careful examination, however, it will be found that the liquid consists chiefly of the condensed aqueous vapour formed by the combustion of the gas with trifling amounts of sulphur compounds, organic matter, and carbonic acid. It is obviously impossible to condense the bulk of the carbonic acid by the means adopted, as cold water will only absorb about its own volume, and warm water even less. For conservatories the absence of smell and condensation of the sulphur products, &c., renders them eminently suitable, but they should never be used in bedrooms, and but cautiously in sitting-rooms. This caution is the more necessary, as the prospectuses of the makers would lead the public to put a misplaced confidence in them. One variety is termed "Sanitary" and another "Hygienic." The patentees of the latter have also the audacity to advertise in a contemporary which devotes itself to health matters, "This being a

Ventilating Stove, it is specially suited for Sick Rooms, Hospitals," &c. As the only change of air produced by it consists in the pollution of the surrounding atmosphere by the stream of carbonic acid evolved by it when in action, the term "Ventilating" is surely ill-applied.

Several asbestos gas fires are to be seen in action, of which one shown by Messrs. Pugh, of Holloway, struck the writer as being particularly effective.

Gas-coke fires have been already alluded to.

Several gas heaters are exhibited, in which, by a novel arrangement, the heat is distributed over a large surface so as to radiate more heat than usual into the room. In many this was done by an arrangement of iron wire netting intermixed with a few pieces of platinum wire, somewhat resembling an ordinary fireguard, and backed in some cases with fireclay. In others a fireclay slab was partially covered in front with fibre asbestos. In all, a row of gas jets plays along the bottom edge and renders the whole mass incandescent. They are certainly effective as heating agents, especially those backed with fireclay, but burn as much gas (15 to 30 feet an hour) as ordinary asbestos gas fires. Gas heaters on this principle are exhibited by Messrs. Browne and Co. of Piccadilly ("The Piccadilly Gas Fire"), Messrs. H. and C. Davis and Co., of Camberwell, Messrs. Ewart and Sons, of Euston Road, Messrs. Leoni, of the Strand, Messrs. Waddell and Main, of Glasgow ("Hislop's Metallic Gas Fire"), Mr. Chas. Wilson, of Leeds, and Messrs. John Wright and Co., of Birmingham. Messrs. Leoni's is particularly attractive, as it is placed in a nickel-plated frame. It has the advantage that the gas does not play on metal. If used with a flue which has a good up-draught, none of these are objectionable from the standpoint of health. The writer's experience is that the upper opening of the chimney usually requires diminishing when it is used to remove gas fumes. All gas appliances have the advantage of being cleanly and saving trouble.

Ventilating Gas Appliances are more worthy our attention. In all of these the fumes before escaping are made to impart a considerable proportion of their heat to a stream of entering cold air in another tube. As a rule, they are superior both from a sanitary and economical point of view to those gas appliances which warm solely by radiation.

Messrs. Deane and Co., of London Bridge, exhibit some ventilating gas stoves by Mr. Fletcher, of Warrington, or "gas fires," as Mr. Fletcher prefers to call them, although on placing the hand in front of the flame, the radiant heat is a mere nonentity. We are sorry Mr. Fletcher says they may be used "with or without a flue."

Mr. G. J. Cox, of Maidstone, exhibits his "Regenerator" Air-warming and Ventilating Stove, with respect to which he makes a similar statement, viz., that "for halls of mansions, vestibules, public rooms, offices, and warehouses, it does not require a flue," an assertion which the health student will hesitate to endorse. One cubic foot of gas produces (when burnt) two cubic feet of carbonic acid (besides other products). When burning ten feet of gas an hour, therefore, this stove will evolve twenty cubic feet of carbonic acid in the same time, or more than an adult man does in twenty-four hours. An atmospheric burner is employed.

Messrs. Ewart and Son exhibit a ventilating gas stove with a ruby glass door, through which the flame can be seen at all times. This stove is also constructed to burn ordinary fuel.

Messrs. J. F. Farwig and Co. exhibit George's Patent Gas Calorigen. This is certainly a very efficient air-warmer, but has the disadvantage that it does not extract any foul air, but only acts as an inlet ventilator. The flame can be seen through a talc door, and the burner swings out for lighting. The tube for supplying the necessary air for combustion is so arranged with regard to that for removing the fumes that only sufficient air for combustion is supplied, and this becoming warmed in its entrance, tends to render the combustion of the gas more complete. By the arrangement adopted the danger of the flame being blown out is reduced to a minimum, and, when the talc door is closed, neither fumes nor unburnt gas can escape into the room, as the gas is completely isolated from the room. When taken direct into the outer air instead of into a chimney, provision is made for the escape of the water formed by condensation, so that it shall not run back into the stove.

Messrs. Geo. Haller and Co., of Lime Street, exhibit Kohlhof's Patent Hot-air Gas Stoves. The fumes are made to pass over as large a surface as possible before escaping, and the escape pipe is as small as possible.

Mr. Hammond, of Chandos Street, W.C., exhibits ornamental warm air-gas stoves.

Dr. Adams' Ventilating Gas Stoves are exhibited both by Messrs. Wm. Harvey and Co., of Glasgow, and by Messrs. John Wright and Co., of Essex Works, Birmingham, and Upper Thames Street, E.C. The latter firm exhibit, in addition, a stove fitted with an asbestos gas fire, and so arranged as to warm a current of fresh air, while the fumes are completely removed.

The Sanitary and Economic Supply Association of Gloucester exhibit various gas heaters designed by Dr. Bond. In the ventilating gas stoves we are sorry to observe the atmospheric or Bunsen burner is adopted, as its liability to blow out either by a down-draught or gust of air in the room renders it unsafe, although giving a little more heat, through the combustion being more complete.

Schönheyder's Patent Sanitary Stove, exhibited by Messrs. Strode and Co., of Cockspur Street, S.W., lights the apartment as well as warming and ventilating. The same firm have a ventilating sun-burner.

Messrs. Taunton and Hayward, of Birmingham, exhibit "Tait's Thermic Ventilator," designed by Mr. Lawson Tait. In appearance it resembles a Tobin's tube, but is double, the fumes passing away through the outer tube, whilst fresh air enters through the inner, and is warmed in its passage. Gas or paraffin is used as the heating agent. For gas, Messrs. Taunton and Hayward supply an atmospheric burner. The danger of this has been adverted to above. Any purchaser of the "Thermic" would do well to substitute an ordinary fish-tail, as this will give off heat enough to warm a moderate-sized room to 60 deg. in cold weather—at least, such is the writer's experience. The longer time required to warm the room is more than compensated by the extra safety with the ordinary burner. With the "Thermic," special precautions should be taken against down-draught, especially when the outlet tube is taken direct into the open air instead of into a chimney, or the fumes may be driven back into the room, and not be immediately perceived. With the "Bunsen" burner the gas might even be extinguished by a down-blow, and the room be filled with gas, thus in a bedroom asphyxiating the inmates.

One merit at least is possessed by smoky fuel—viz., that a down-blow is at once manifested, and steps taken to remedy it, while with any kind of smokeless fuel it may—at any rate temporarily—escape notice.

Most of the most important objects of interest in the way of warming appliances have now been noticed. Kitchen ranges scarcely possess a medical interest, although they may be made to serve as hygienic appliances, viz., by means of a hot air chamber placed behind the range to distribute pure warm air to some or all the rooms of a house.

Gas Warming appliances have been mentioned. Gas Lighting appliances are also freely exhibited, also Gas Governors, Gas Making Machines, Gas Engines, and even various ornamental globes.

Ventilating appliances are also well represented.

Last but not least, we must not omit to notice Baatsoh's Slag Felt, made from the Silicate Cotton, manufactured by Mr. Fredk. Jones, of Kentish Town. It is perfectly incombustible in the hottest fire. It is also sound proof to some extent as its texture is loose, somewhat resembling cotton wool. It may advantageously be used for sound proofing partitions or plugging floors in hospitals and other public buildings where its fire-proof properties will render it an advantage.

In speaking of the "Controlled Combustion" basket, brought out by the Coalbrookdale Co., it should have been added that it closely resembles one long ago made by Mr. F. Edwards, of Great Marlborough Street, a fact which the Company might have been courteous enough to acknowledge. This and many other appliances will be found described in Mr. Edwards' work on "Warming and Ventilation."

AUGUSTUS COX.

At the Central Criminal Court last week Mr. Montagu Williams applied to Mr. Justice Denman that the trial of Dr. Lamson might be postponed to the next sessions, in order to afford time for further inquiry. No objection was offered by the prosecution, and the application was granted.

PROFESSIONAL AMENITIES.

ACCORDING to pessimist views of the condition of the medical profession its members are divisible into two great classes, either of which may with equal justice be regarded as embodying the characteristics that are least admirable as human traits; while at the same time the one class is ever at variance with, or engaged in abuse of, the other. Veil it as we may the fact remains only too apparent; and so long as it continues to be so, it is futile to look for any real improvement in the status of the profession. What hope can be entertained that the public will think highly or honourably of those who are constantly being abused by members of their own calling? What faith can be felt by outsiders in a body of men not one of whom can be certain that he may not sooner or later be the object of attack by a fellow-worker in the field of medicine? It is folly to imagine that the world is regardless or ignorant of blots of this kind defacing medical practice, or that it is not mightily influenced by them in the estimate it forms of the profession as a whole. Scarcely a prominent trial passes without some one or more exhibitions of angry feeling between representatives of medicine; never, it may safely be avowed, are opposing opinions uttered in courts of law by medical men without a show of bitterness that calls a blush to the cheek of every earnest well-wisher to the profession; and yet, while this is so, we are constantly hearing complaints of the light regard in which the profession is held by the laity.

We have no desire to renew discussion on the trial

just concluded at Sunderland ; but we would refer to it as a recent proof of the truth of the statements made above, and as offering an example of the uncharitableness of medical men towards medical men. It would appear from this and similar instances, that in the heat of controversy members of the profession not only forget the respect due as much to others as to themselves, but they even also for the time ignore that they are champions of professional honour itself. It is not enough for them, apparently, to express their disagreement on scientific questions merely, but in very many cases they voluntarily add to this an element of personal abuse which is pre-eminently out of place, and which does incalculable harm by exciting in the public mind a feeling of contempt towards not only the authors of the impropriety, but towards the profession of medicine as well. Necessarily this reacts to the great detriment of all attempts in the direction of improvement, and we do not hesitate to allude to it as the most potent factor determining the inferior position held by our profession at the present time.

At certain periods of the year it is customary for hospital orators to impress on the world a notion of the dignity and honour, and nobility of the physician's calling, and to insist on the elevated status proper to the professors of medicine in virtue of their calling. It is quite conceivable that constant iteration of these interesting details might have the effect of creating a firm faith in their reality, were there not a miserable succession of petty differences and vindictive utterances on the part of members of the extolled profession chronicled in every interval separating such rhetorical displays. As it is, can we wonder that a public, treated on the one hand to loudly flourished expositions of a theoretical greatness, and on the other to a practical demonstration of the hollow unreality of the expressions employed at introductory ceremonies, refuses to recognise the claim set forth, and elects to judge the profession of medicine by the acts of medical men themselves. The consequence is inevitable, and we shall better perform the duty we owe to the profession by outspoken condemnation of the faults which so seriously affect it, than by wilfully blinding ourselves to their existence. In one sense, perhaps, it is impossible to hope for any speedy and sufficient amendment ; so far, that is, as the evidence of experts in courts of law is concerned. The state of science is such as to admit of two widely differing opinions being entertained on the subject of many diseases with the existence of the best possible intentions on the part of each witness. Even here, however, the profession could by its own spontaneous action, so alter the conditions surrounding cases of this kind as to remove much of the opprobrium attaching to existing customs. But this is a question too complicated to be dealt with in the present leader. Omitting all such instances, and for the moment accepting them as inevitable, there still remain that extensive class of cases, in courts and out of them, in which by innuendo, by actual attack, or by thinly disguised references, one medical man seeks to affect the estimation in which a brother practitioner is held. For this kind of sin we can find or admit no possible excuse ; it

is despicable, unmanly and utterly indefensible. Even if the object of attack is deserving the unfavourable notice he receives, it should never proceed from a "brother chip ;" it is not by exhibitions of petty jealousy, of spite, and of envy such as is thus evidenced, that the truth of 1st-of-October orations can be enforced ; such proceedings do nothing more than show up two miserable pretenders to professional excellence, in place of the one whose act was the original or fancied cause of offence ; and the public, the great public, that is the final arbiter of our deserts, is fatally quick to recognise every blemish of the kind, and to take sure note of it when adjudicating on the claims of "the noblest profession in the world."

We have ventured in all humility, to broach this subject because it is one that is daily growing in importance ; and because we are daily more and more conscious of the irretrievable injury being done through the causes we have mentioned ; action, speedy, sure, decided, is called for ; and the initiative must be taken by some one.

OUR COLLIERIES.—II.

WE return to the theme commenced in our issue for Jan. 25 in the hope of fully ventilating and wiping out a disagreeable and malodorous subject ; and we are glad to report that at the colliery where, at the time of our writing, so much filth and squalor reigned triumphantly, a marked improvement has already taken place, so that our exposure of the evil has not been in vain. Manager, doctor, and nuisance inspector, are stirring, and even that cumbersome body, the Local Government Board, has been moved into "inquiry." Our object, therefore, in reverting to the subject is to keep it alive, so that it may not be allowed to pass from the public gaze until so abominable a state of things shall have attained to prompt and effective remedial action on the part of all concerned.

To the owner and officials of the colliery in question it may have appeared somewhat unjust on our part to single it out for exposure, when the same description, almost to the letter, would equally apply to one-half of the collieries in the country ; but to effect practical reforms examples must be adduced, and we are satisfied with the result so far. We are, of course, unaware whether our commissioner travelled over in whole or in part the same ground lately traversed by the Local Government Board inspector, Dr. Speer ; but if that gentleman's travels did not extend there, they ought to have done, for our commissioner found at some collieries in Dr. Speer's track, not only a great deficiency in closets and rubbish heaps, or "middens," but the middens that were, were "choke full," and the refuse, filth, or waste was often scattered or piled up in the streets or roads. On inquiry as to the "why" of this, the same reply was given in every case—"Farmer Smith's, or Farmer Jones's, or the colliery carts will come some of these days, when they have leisure, or when it is needed for the land." This may be a very convenient arrangement for farmers Smith and Jones, but its results upon the health of the inhabitants of the colliery houses and the other houses is another question.

And that the duty of regular periodical cleaning of the filth stores should be nobody's business, but left in a haphazard way, to be discharged by so many apparently irresponsible people at their "leisure" is, we consider, something astounding under the operation of the Sanitary Act; and more particularly as this Act, whether well or badly administered, entails a heavy tax upon the innocent and powerless rate-payers.

We have put ourselves to no little trouble in trying to sound to the bottom the mysteries which surround this Dirt business, and we now propose to give our readers—and through them the general public—the benefit of our investigations.

The deliberate opinion formed by us as the not hasty result of these investigations is that the roundabout resistance of "red-tape" and ignorance at the central department—the L.G.B.—and the do-nothing, or, as little-as-possible policy of resistance of the local authorities—the boards of guardians and others interested—are the reasons for this gross obstruction of all law, statute and sanitary, written and unwritten. And so long as the appointment of health officers remains to be disposed of as at present, then so long will this sanitary question be like other "burning" questions—one of national import and disturbance.

In drawing public attention to sanitary derangements and deficiencies in villages or townships inhabited by coal-miners it might be urged in reply to our statements thereupon that many communities, civil and rural, throughout the land have to suffer a state of things exactly similar to that exposed by us; yet no great outcry follows. If anyone were so simple as to reason thus, the threadbare answer of two blacks never making a white is to him a sufficient reply. Moreover, this would be an additional reason for an inquiry into the causes of the drowsiness of the responsible authorities, which inquiry ought to be full enough to arouse those authorities into life and activity. Viewing off-hand the ample machinery employed and the heavy expense entailed in working the Sanitary Act, there ought to be no neglect of duty, no delay in its execution, and no complaint by or on the part of any person concerned in the operation of this Act. The theory is, no doubt, like many others faultless, but the practice entirely nullifies the theory. The Act proves to be an expensive failure because there are too many departments concerned in enforcing it; and the common saying about everybody's business being nobody's business is aptly illustrated thereby.

THE NOTIFICATION OF INFECTIOUS DISEASES IN IRELAND.

We announce with much satisfaction that the differences of opinion between sanitarians and physicians in Ireland on this subject, which received so much attention from us during the last Parliamentary Session, are in a fair way of settlement, and that a Bill has been framed which, while it will fully protect the physician's position, will effectually provide for the informing of the sanitary authority as to the existence of infectious disease. This Bill will, we believe, receive the support of all parties in the profession,

and, we venture to hope, will not be resisted in Parliament. It is as follows:—

Whereas it is desirable that due notice should be given to the sanitary authorities in Ireland of the existence of dangerous infectious diseases within their district:

3. If an inmate of any building used for human habitation is suffering from any of the infectious diseases, the person in charge of such inmate, or, if such person be prevented by disease or otherwise, the occupier or any other person having the management or control of such building, shall forthwith cause notice thereof to be given, by letter or otherwise, to the sanitary authority of the district in which such building is situated, as nearly as possible in the form contained in schedule B to this Act.

4. Every medical practitioner attending or called in to visit any person suffering from any of the diseases set forth in this Act, *may, if he think fit*, notify the occurrence of such case of disease to the sanitary authority of the district in which the person suffering from such disease resides; and every medical practitioner so notifying shall forthwith fill up, sign, and deliver, or cause to be delivered, or shall transmit by post to such sanitary authority a certificate stating the name and place of residence of the patient, and the nature of the disease from which such patient is suffering; and shall also fill up, sign, and deliver to the person having charge of such patient, or to the person having charge of the building in which the patient resides, a further certificate, the production of which certificate shall be a good defence for such person against any penalties for breach of the terms of this Act.

5. The sanitary authority shall supply gratuitously to every registered medical practitioner resident or practising in its district, forms stamped for transmission through the post, for certifying by such medical practitioner of the particulars herein-before mentioned of cases of infectious disease attended by him; and the medical attendant shall furnish to the person in charge of the patient, and also the sanitary authority, the certificate herein-before provided, and the sanitary authority shall pay to every medical practitioner who shall duly furnish to it any such certificate, a fee of two shillings and sixpence in respect of every such certificate so furnished to it.

7. Any person who shall neglect to give or deliver, or cause to be given or delivered, any notice required to be given under this Act, or who shall knowingly give false information concerning any of the particulars required to be given to the sanitary authority, shall be liable to imprisonment for a period not exceeding two months, or to a penalty not exceeding *five pounds*, to be recovered in the same manner as penalties under the Public Health (Ireland) Act, 1878.

8. Every sanitary authority shall take all necessary means to make the provisions of this enactment generally known by causing a copy thereof to be affixed at the principal door of every church and chapel in its district to which such notices are usually affixed, and by publishing the same by advertisement in some one or more of the local newspapers circulated in its district, and by such other means as it may consider advisable.

SCHEDULE A.

*The following are those diseases termed infectious in the meaning of this Act:—*Typhus fever, typhoid or enteric fever, relapsing fever, variola or chicken-pox, small-pox, scarlet fever or scarlatina, measles, erysipelas, diphtheria, cholera, whooping-cough, puerperal fever.

It will be observed that the Bill throws the entire responsibility of notification on the custodian of the patient, and not, as was proposed by Mr. Gray's Bill of last year, on the physician. It leaves a medical man entirely untrammelled and unimpeded in his intercourse with his patient, and thus obviates the objection to Mr. Gray's and Mr. Hastings' Bills, that the physician, if obliged to notify, would be excluded from every case the infectious nature of which was sought to be concealed. But this Bill recognises the fact that it is the moral duty of the doctor to inform the custodian of the patient that the disease is infectious, and that he is the most efficient agent for the

notification of that fact to the sanitary authority, and it makes provision by which the physician will be induced to take upon himself the duty of notifying, and will be remunerated for so doing. By the 4th section the medical practitioner is allowed to undertake to notify or not, just as he pleases, but, if he does accept the duty, he is bound to perform it effectually, and he will incur penalties if he fails to do so. Of course, when the medical attendant agrees to notify, and becomes bound to do so, it is right that the custodian of the patient should be free from all liability in the matter. Therefore the medical attendant is provided with a form in three parts. One of these is already stamped for post and directed to the Clerk of the sanitary authority, and it is only necessary to fill in particulars and drop it into the nearest post-office or pillar-box. The second part of the form is an undertaking to notify, which the physician gives for the safety of the custodian, and this the physician fills up, tears off, and hands to the said custodian, and it protects that person from any prosecution or penalties to which he would otherwise be liable in case he omitted to notify. The third part of the form is a record of the transaction to be retained by the physician for his own information. The working of the arrangement will be that, in case the sanitary authority comes to know of a case of unnotified infectious disease, it prosecutes the custodian of the patient, who gets off scot free if he can show the undertaking of the physician that he would notify, and then the medical attendant is himself answerable for the omission. As each notification will be a fee of half-a-crown to the physician, and as the transaction will be extremely simple, it is anticipated that almost every case which needs it will be notified, and very many cases which would be unheard of if the doctor were made the sanitary detective will be recognised early in the disease and properly cared for.

We cordially approve of the Bill, and hope that all parties will unite in supporting it. Already it has received the sanction of the Irish Medical Association and the Dublin Branch of the British Medical Association, and no doubt it will also be approved by the Irish colleges.

Notes on Current Topics.

Widows and Orphans of Medical Men.

How often do we read in our medical journals appeals for the widows and orphans of deceased *confrères*—appeals the most distressing, supported by too strong testimony, that without aid the relict and children must starve or go to the workhouse! How long will this state of things continue? Until the end of time, we fear, unless we can rouse in the hearts of every married medical man the honourable feeling, that it is his imperative duty to make some provision for those who are dependent on his brain and on his health for support. Love and affection sound well, but there can be no true love or affection when a medical man places those who have been dear to him in the humiliating position of supplicants for charity from their fellows. Can a medical man make provision? He can to a certain extent. He can make such provision that his wife will not have to

figure in the medical journals; he can leave more than will be realised by the voluntary contributions of those who are willing to help a brother in distress. There are numerous medical charities. A subscription of one guinea, or even less, a year, will make a better provision. A yearly premium of five pounds a year in some good insurance company—and there are a large number of safe insurance companies—will insure at death a handsome sum in comparison with what is raised by these appeals.

There are few medical men who cannot afford five pounds a year for an investment of this nature. The poorer a medical man is the more necessity is there for his making an effort to leave something to his children in case of his death. It is a great ethical question whether a man should marry who cannot make some provision for those he may leave behind him. There is no use discussing this subject, for there is a foregone conclusion in connection with it—viz., no matter how strong the arguments might be against the marriage of one poor person with another, the marriage would be consummated all the same. The potential power of what is called love is so great that it destroys all reason and experience. We can only urge those who are now in seeming health to consider their financial position, and cast up what the incomes of their wives or children would be if death terminated their work to-morrow. If their assets would be *nil*, then we say they should at once endeavour to provide something, however small, against the inevitable. What method that provision may take we need not advise, for there are so many open, that there is little excuse for any objections on that ground.

The Causes of the Dangers of Chloroform.

DEATHS from chloroform administration take place. It is the duty of surgeons to minimise the dangers, and to find out the causes why chloroform is, in some cases, so fatal. At the Chirurgical Society, Paris, December 21st, M. J. L. Championnière introduced this subject. In the course of his experience, he remarked that the accidents met with in chloroform administration were due to the bad quality or impurities of the chloroform. Chloroform produced more bad results now than in the early days of its use. In certain cases he had to use more chloroform, from 100 and 150 to 200 grammes, to produce anaesthesia. With a pure, good chloroform, this large quantity was not necessary.

M. Championnière proposed a very simple means of testing chloroform. If permanganate of potass be added to chloroform, the solution will pass from red to green. By distilling and re-distilling, until this reaction is no longer procured, a pure, sweet liquor may be obtained, which will possess high anaesthetic power, and this preparation may be used without risk.

M. Berger agreed with M. Championnière. Pure chloroform had a sweet smell, and did not stain; whilst impure chloroform had an irritating smell, and left a stain on linen or paper.

M. Perin (Maurice) thought it important to have good chloroform, but it was not easy to obtain a pure product. Chloroform, by inducing the anaesthetic state, must always give rise to the dangers of sudden death.

If pure chloroform can be obtained—and we believe it

can—then it is the duty of all who use this anæsthetic to ensure that what they are about to use is free from impurities. Familiarity with danger begets a certain amount of contempt for the instrument of danger ; but, looking at the individual importance of a pure anæsthetic, and the risks of chloroform, the advice of M. Championnière is well worth following. His test is simple, and easy of adoption.

Do the Inferior Crustaceans distinguish Colour ?

SINCE Sir J. Lubbock published his experiments on the perception of colour in ants, this question has attracted the attention of naturalists. Mr. M. C. de Merjkowski has examined the colour perception of the lower crustaceans. The following is an abstract of his researches, presented to the French Academy of Science :—

Mr. C. de Merjkowski selected *Dias Longiremis* and some larvæ of *Balanus* for his experiments. In a dark vase the crustacea were scattered in all directions : when, by means of a window, light was allowed to enter, they collected near the window. When a mono-chromatic light entered, they hastened to it, the same phenomena taking place with other coloured lights. From this Mr. M. C. de Merjkowski concludes they are not colour-blind for any individual colour. In order to determine whether they saw light as we see it, he had two windows placed at an angle of 40 degrees, through which various coloured lights entered. If by one opening a white light, and by the other a mono-chromatic colour entered, the crustacea always preferred the first. When a dark colour and a light colour were passed into the vase, they always preferred the latter. When two coloured rays of equal clearness were passed into the vase, the crustaceans divided into two bodies, some preferring one light, the others selecting the other. They distinguish the intensity of the vibrations of colour or matter ; they perceive colours as light ; but they do not distinguish, as we do, colour as colour.

The Hygienic Value of the Electric Light.

THE hygienic value of the electric light has been made the subject of a recent communication to *La Nature*, a French scientific journal, by Dr. Javal. Upwards of two years ago, October 29, 1879, we drew particular attention to the fact, after having instituted a number of careful observations in the reading room of the British Museum, and from experiments made with a view of determining the value of the electric light, we stated our conviction of its superior visual qualities as compared with gas and other sources of illumination, and also that there was absolutely no danger to the eyesight from its use. There can, then, be no excuse for the statement made by our neighbours on the other side of the Channel, that “ the hygienic qualities of the electric light have not hitherto been appraised at their real value.”

M. FANO, in a communication to the Academy of Sciences, shows that the choroid membrane of the eye has a more important function than that commonly ascribed to it, and has a decided influence on the distinctness of vision.

Improper Certification of Death.

THE question of death certificates has always been one on which the profession is likely at particular times to be much exercised. Were it possible in every instance to draw a hard and fast line respecting the necessity for granting them in the way that the law imposes, no difficulty would be, or need be, encountered. Unfortunately, however, there are in the experience of every medical man occasions on which it becomes all but impossible to strictly follow out the legal regulations without incurring other risks that, to young practitioners especially, would be best avoided ; such, for instance, as loss of popularity, or the gaining a character for unwillingness to “ oblige ” patients and their friends by “ straining a point ” in their favour. An admirable illustration of what we refer to is afforded in the accounts published of the proceedings instituted against Mr. John Coryn, a surgeon at Brixton, for having falsely certified that a child was born dead. From the evidence it appears that this was not the case, and that the infant had survived some time ; but at any rate it was dead when Mr. Coryn paid his first visit after the confinement, and when he gave the certificate complained of. The prosecution was directed by the registrar-general, and defendant was fined 20s. and costs. The affair is important in connection with the admission of Mr. Coryn to the effect that he had occasionally committed a similar indiscretion, being always under the impression that by so doing he was in no way acting either illegally, or in an unusual manner. Further, he contended that his sole motive was a desire to relieve his poorer patients of worry and expense, since the question of burial was a less costly matter in the case of children certified as stillborn.

We may at once assume that a practitioner placed in the position of attending a poor woman whom he delivers of a child that, dies quickly after its birth is actuated by the kindest intentions when he grants a certificate of stillbirth. But none the less he commits a grave offence, and one, moreover, from which he should abstain, even though no legal penalty were attached to its performance. When he is conscious that a living child is born, nothing can justify his personal testimony to the contrary ; such action, however meritorious the end to be attained by it, must react detrimentally to its author, and also to the welfare of the profession he should be at all times zealous to protect from every suspicion of wrong doing. In the instance we refer to an offence against the law was committed, and much as we may sympathise with Mr. Coryn's honest anxiety to relieve the burdens of his poorer patients, we cannot but think he has fully deserved the punishment awarded to him. Medical men should always, and even at all costs, adhere strictly and closely to the forms prescribed in Acts of Parliament ; and in nothing so particularly as in the granting of certificates, on the accuracy and *bona fides* of which so much of national importance depends.

DIPHTHERIA caused thirty-four deaths throughout the United Kingdom last week, whilst in Paris alone there were seventy-four deaths from this cause, thirty-seven in Berlin, and forty-seven in New York.

St. Bartholomew's Hospital.

THE resources of the staff, visiting and resident, of St. Bartholomew's Hospital, have, it has long been known, been most unduly taxed by the increasing demands made by the constantly growing numbers of those who seek the benefits conferred by the charity. In order to meet the pressing needs thus created important changes are to be made in the *personnel* of the hospital by the addition of one surgeon and one assistant-surgeon to the senior staff, and of four house-surgeons to the existing resident staff. There will thus be two important vacancies on the surgical side of the house, and among the candidates will probably be several gentlemen who have long been devoted to the service of the hospital in one way or another. The present senior assistant-surgeon, Mr. Morratt Baker, it may be assumed, will naturally be appointed to the newly-created surgeoncy, thus leaving two new assistant-surgeons to be selected from the applicants who will enter for them.

Ambulance Service for London.

ON Thursday last an influential meeting of medical men and others interested in the movement on foot to provide the metropolis with a regularly-appointed and controlled ambulance service, was held in the United Service Institution. The Duke of Cambridge occupied the chair. Sir Wm. Gull moved, and Mr. J. H. Buxton, chairman of the London Hospital, seconded a resolution to the effect that "it is desirable to form a hospital and accident ambulance service for London." This was carried unanimously, and a committee was then formed to carry out the scheme. The system to be adopted has been carried out in New York with admirable success, and although, as Mr. Holmes observed, if all policemen were members of the College of Surgeons they would still commit mistakes in diagnosis, there can still be no doubt that the new ambulance service will go very far to reduce the number of serious blunders committed in dealing with the accidentally hurt.

To Mr. Croesman must be ascribed the credit of introducing the ambulance service to this country, as it is by his efforts chiefly that the scheme has been so far advanced to completion.

Indian Medical Items.

THE great religious fair at Allahabad has come to an abrupt end. In spite of all "sanitary" precautions cholera broke out among the vast crowds assembled there. The disease does not seem, however, to have caused much mortality at the fair, but by orders of Government the pilgrims had to disperse. It remains to be seen whether in the present, as on so many former occasions, the disease in epidemic form will follow the various routes taken by them.

The first report on the working of the Contagious Diseases Act in the island of Bombay has just been published, and the Government resolution upon it takes an extremely favourable view of the benefits conferred by the Act in the diminution of disease.

Modern Dress.

MR. FREDERICK TREVES, F.R.C.S., assistant-surgeon to the London Hospital, will deliver a lecture on Saturday, February 25th, at 4 o'clock in the afternoon, at the Town Hall, High Street, Kensington, on "The Dress of the Period." Dr. Andrew Clark is announced to take the chair, and the proceedings will be under the auspices of the National Health Society. The lecture is intended to deal with the follies and absurdities committed in connection with modern clothing, and also with the serious physical injury caused in many cases by following the dictates of fashion.

The London Water Supply.

DR. FRANKLAND reports that during the past month the Thames water sent out by the West Middlesex and Southwark Companies was much polluted with organic matter, whilst that distributed by the Grand Junction and Lambeth Companies, though less so, was of worse quality than any supplied since March of last year. The Grand Junction contained moving organisms. The water drawn from the Lea by the New River and East London Companies, although better than the average Thames water, was, with the exception of that sent out by the East London in October, inferior to any supplied from the same source since March last. On the contrary, the deep-well water delivered by the Kent and Colne Valley Companies, and by the Tottenham Local Board of Health, was, as usual, of excellent quality for drinking, and the Colne Valley, being softened with lime, was also well fitted for washing and all domestic purposes.

The Jacksonian Prize.

It is rumoured that five essays have been received in competition for the Jacksonian Prize, 1881, the subject for which was "Pathology and Surgical Treatment of Diseases of the Hip-joint." For the present year the subject is "Wounds and Other Injuries of Nerves: their Symptoms, Pathology, and Treatment." Competing essays must be delivered on or before December 30th next.

Protection of Cattle by Inoculation.

At a farm near Méln, in France, experiments were recently made by M. Pasteur, in the presence of a large number of scientific gentlemen, on the duration of the action of anthracic vaccine as applied to sheep. It will be remembered that six months ago M. Pasteur vaccinated a number of sheep with anthracic vaccine, the immediate result being to preserve all those sheep from anthracic virus, whereas sheep not so vaccinated succumbed within twenty-four hours. The question was, how long the influence of such vaccination would last. Four unvaccinated sheep were inoculated with anthracic virus, as also four of the sheep vaccinated six months ago. Two of the unvaccinated sheep expired within twenty-four hours, and the other two subsequently; whereas the sheep vaccinated six months ago effectively resisted the action of the virus. Another noteworthy fact was ascertained: a lamb, the offspring of a vaccinated sheep, was inoculated with the virus; it expired within twenty-four hours,—thus proving that the protective influence through "vaccination" is not

transmitted hereditarily in this instance, any more than is the similar protective power of vaccine lymph.

Professor Parker's Lectures.

PROFESSOR W. K. PARKER'S lectures on the Morphology of the Mammalian Skull will take place at the Royal College of Surgeons in the following order:—

1. February 6th—Introductory. On the vertebrata as a group, and on the vertebrate embryo. 2. February 8th—On the development of the endoskeleton and a comparison of its cranial and spinal regions. 3. February 10th—On the superficial cartilaginous skeleton, labial, oral, and pharyngeal; on the limbs; and on the dermal (bony) skeleton. 4. February 13th—The endocranium, proper, in its gradation and development throughout the vertebrate series. 5. February 15th—The histological changes undergone by the endocranium; (a) The membrano-cranium, (b) the chondro-cranium, (c) the chondrosto-cranium, (d) the osteo-cranium. 6. February 17th—The sense capsules of the vertebrata. 7. February 20th—The visceral arches and cranial nerves in the branchiata. 8. February 22nd—The visceral arches in the abbranchiata; their abortive development and modification in relation to the sense capsules, especially in the mammalia. 9. February 24th—Recapitulation and conclusion.

Deaths under Chloroform.

AN inquest was held last week, at Malvern, on the body of a man, *æt.* 51, who died while under chloroform. Deceased had sustained a dislocation of the shoulder, and he waited upon Mr. Haynes, surgeon, who decided to administer chloroform; but, before doing so, examined deceased's heart. Soon afterwards, deceased's legs became convulsed, and he held them, but death took place in a very short time. Mr. Brown, surgeon, who made a post-mortem examination, said that deceased was in such a state of health that he might have died at any moment. The jury returned a verdict of "Died from natural causes, accelerated by chloroform judiciously and properly administered"; but some of the jury deprecated the practice of the profession in putting persons under the influence of chloroform "single-handed."

A case is also reported in the daily papers of Mr. T. Fenton, of Broughty Ferry, who was about to undergo an operation for sympathetic ophthalmia. It had not been administered many minutes before he died.

A third case of death under chloroform occurred at the Royal Free Hospital.

Poisoning.

ON Thursday week Dr. Stewart, coroner for Monaghan, held an inquest upon the body of a woman, aged 76 years, who came by her death under peculiar and melancholy circumstances. A marriage was being celebrated in the house of the deceased, and when dinner was over the company retired to the barn to have a dance. The deceased woman asked a servant girl, who was clearing away the dishes, to have a glass of wine, and, the girl consenting, the old woman took from the cupboard shelf what she supposed to be a bottle containing wine, but which actually contained carbolic acid. Before giving it

to the girl she put the bottle to her mouth to taste it, said it was very bitter, and immediately felt unwell. The old woman never recovered consciousness, and died at about eight o'clock. The jury returned a verdict of "Death from accidental causes."

The Queen's University Dissolved.

AN order of the Lord Lieutenant and Privy Council appears in the *Dublin Gazette*, containing the following passages:—

Whereas, Her Majesty has been pleased to found a University, to be known as the Royal University, under the provisions of the aforesaid statute, by charter dated the 27th day of April, 1880, which said charter vests in the said Royal University the power of conferring degrees as aforesaid;

And whereas the said University is now in a position to confer degrees;

Now we, the Lord Lieutenant General and General Governor of Ireland, by and with the advice and consent of the Privy Council in Ireland, in pursuance and by virtue of the University Education (Ireland) Act, 1879, and of every power and authority enabling us in this behalf, do, by this order in Council, fix the 3rd day of February, 1882, as the day on which the said Queen's University in Ireland shall be dissolved, and do order that from the said 3rd day of February, 1882, the said University shall stand and be dissolved accordingly.

Given at the Council Chamber, Dublin Castle,
on the 31st day of January, 1882.

Anthropology applied to Purposes of Justice.

THE police take photographs of our criminal classes, and there must now be a great accumulation of these interesting physiognomical studies. It must be difficult in London to seek out for any individual photograph; in certain cases this may be necessary. In Paris this difficulty has been considered. M. Bertillon purposes to arrange the photographs according to height of individuals. Thus, in one division would be placed those who were 1m. 55' to 1m. 60'; in another those who were 1m. 60' to 1m. 65'.

Sub-divisions might then be made according to colour of eyes, length or shape of head, special deformities, as loss of hand, finger, pock-marks, &c. We recommend this suggestion of M. Bertillon to the head of our Criminal Investigation Department, Mr. Vincent.

Queen's College, Belfast.

IT is stated that the number of students entered for the present winter session amounts to 565, being an increase of about ten per cent. upon the previous winter session. Of these, 355 have been enrolled in the Faculty of Medicine, making the medical school of this College the largest in Ireland.

WE learn with delight that an anti-vivisectionist who subscribes £20 yearly towards carrying on the anti-scientific agitation has been fined for maltreating an "unoffending" animal in his possession.

Sir George Owens and the Dublin Hospitals Board.

IN quoting last week a portion of an article from the *Freeman's Journal* we inadvertently included a paragraph which reflected on Sir George Owens' fitness for a seat on the Board of Superintendence of the Dublin Hospitals. The objection of the *Freeman* to Sir George Owens is simply that he is not of the approved politico-religious colour, with which objection we have nothing to do, nor have we the least sympathy with the opinions of the *Freeman* on the point. We, therefore, regret that this portion of the quotation was inserted, inasmuch as we were thereby made to appear hostile to Sir George Owens' appointment, which we are not. In our opinion, he is better suited for the position than the majority of the members of the Board; and we hope he will distinguish his appointment by stimulating that conclave to activity.

Homœopathy.

AT the meeting of the South-Western Branch of the British Medical Association the subjoined resolutions were passed unanimously:—

1. That this meeting desires to express its entire disapproval of the views, in relation to consultations with homœopathic practitioners, expressed by the readers of *Addresses in Medicine and Surgery* at the annual meeting of the Association at Ryde in 1881.

2. That this meeting desires to direct the attention of the Committee of Council of the Association to the resolutions in regard to homœopathic practitioners passed at the annual meeting of the Association in 1852, and re-affirmed at the annual meetings of 1858 and 1861; and now calls upon the Committee of Council to put in force as speedily as possible Bye-law 3 against homœopaths and all members of the profession who assume designations implying the adoption of special modes of treatment.

Funeral of the Queen's University.

THE dissolution of the Queen's University in Ireland was on Friday marked by a novel and strange spectacle. It occurred to the students of the Queen's College, Belfast, that the occasion demanded some demonstration, and that that demonstration could not take a fitter form than that of a mock funeral of the University, the untimely end of which is much regretted in the North. The idea thus conceived was carried out on Friday. A coffin was paraded, and following was a long line of youthful mourners. Some of the students wore their gowns, and some mourning bands in the form of white pocket handkerchiefs—in fact, these were the "semblance and suits of woe," but it is to be feared there was no more. When the "funeral" procession reached the College grounds, where the grave was dug, an oration extolling all the virtues of the deceased was delivered, which contained more truth than is sometimes to be found in funeral orations. Then, to the solemn strains of the "Dead March in Saul," the defunct University was laid to its rest. In the evening the Royal University was burned in effigy.

THE overthrow of the Gambetta Administration involves a loss to science in the removal of Dr. Paul Bert from the Ministry of Public Instruction.

The Laburnum Poisoning Cases.

CONSIDERABLE interest and discussion have been excited in the North Riding of Yorkshire relative to the deaths by poisoning of two little girls at Slingsley last month; and the coroner's inquest, which has been twice adjourned, has brought out by conclusive evidence the fact that death in both cases resulted from swallowing the berries of the laburnum. This tree is such a common favourite in gardens that a knowledge of its deadly characteristics cannot be too widely known, and children be warned against its seductive fruit. Much care has been taken in the investigation of these cases, and by a series of elaborate tests, Mr. Fairley, public analyst for the North Riding, obtained good evidence of the presence of cytisine, the poisonous alkaloid present in the seeds, bark, leaves, flowers, and all parts of the *Cytisus laburnum* (the common laburnum tree). Cytisine is a substance having a bitter taste, and distinguished from many other alkaloids by its insolubility in ether, chloroform, benzol, and carbon disulphide. Most of its salts or compounds with acids are uncrystallisable, excepting the nitrate, which crystallises readily. It gives well-marked reaction with certain re-agents, such as bromine water and solution of iodine in potassium iodide, &c. Lastly, cytisine is very poisonous, and Mr. Fairley obtained by extraction with alcohol from each of the stomachs a substance which after purification possessed all the above properties. A very small portion of the alcoholic extract from the stomach of the elder child administered to a mouse caused its death after a few hours. The case presents one singular feature of great interest to the profession, for although many instances have occurred before of children being poisoned by eating the seeds or some other part of the tree, this is the first authenticated case in which death has followed, and where a regular inquiry has been made into the case. At the conclusion of the inquest, the jury expressed a desire that the tree from which the children had eaten should be rooted up, to which request the owner promised to at once accede.

Modified and Natural Small-pox.

WE may draw special attention to the correspondence in our present issue between Dr. Buchanan and Mr. P. A. Taylor, M.P., on the subject of the modification of small-pox. Much interest will be felt in the subject on account of Dr. Buchanan's professional reputation, and from the nature of the evidence he adduces to prove his conclusions.

The Liabilities of Counter Doctors.

A CHEMIST and druggist of Kidderminster has been sued in the County Court by a victim of his counter-practice in surgery, and mulcted in the full damages recoverable—viz., £50, with costs. The plaintiff had applied to the defendant for something for his finger, in which there was a deep-seated abscess. The case was treated in the common counter-practice fashion, and the finger was permanently disabled.

Obligatory Vaccination in Switzerland.

THE *Gazette Hebdomadaire* says that, during the passage of a new law on epidemics the Swiss National Council adopted by ninety votes against twenty-three the prin-

ciple of obligatory vaccination. Every infant born in Switzerland must, according to this law, be vaccinated during the first year of its life, or at latest during its second year; and infants born out of Switzerland, if not previously vaccinated, must submit to the same rule. No child can be permitted to frequent a public or private school without a certificate of vaccination.

DR. ARCHIBALD H. JACOB, Surgeon-Oculist to the Lord Lieutenant, and formerly Ophthalmic Surgeon of the City of Dublin Hospital and the Dublin Eye and Ear Infirmary, has been appointed Ophthalmic Surgeon to the Richmond Hospital, Dublin, *vice* Dr. C. E. Fitzgerald, Ophthalmic Surgeon to the Queen, who has resigned.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their population were—Derby 17, Leeds 18, Edinburgh and Hull 19, Bradford, Sheffield, Portsmouth and Leicester 20, Wolverhampton and Halifax 21, Bristol, Glasgow, Norwich, and Newcastle-on-Tyne 22, Birmingham, Preston, Blackburn, and Cardiff 23, Manchester and Bolton 24, Brighton, Salford, Nottingham 25, Oldham, Huddersfield, London, and Plymouth 26, Sunderland 27, Liverpool and Birkenhead 28, Dublin 35.

IN the principal foreign cities the rates of mortality per 1000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 40, Bombay 34, Paris 29, Geneva 29, Brussels 23, Amsterdam 25, Rotterdam 26, The Hague 26, Copenhagen 29, Stockholm 22, Christiania 25, St. Petersburg 48, Berlin 23, Hamburg 29, Dresden 25, Breslau 29, Munich 35, Vienna 30, Prague 34, Puda-Pesth 37, Naples 28, Turin 29, Venice 25, Alexandria 31, New York 32, Brooklyn 25, Philadelphia 24, Baltimore 26. No returns were received from Madras, Rome, and Lisbon.

IN the large towns last week the highest annual death-rates per 1,000 from scarlet fever were 3.6 in Hull, 3.5 in Sunderland, and 2.4 in Brighton; from whooping-cough, 2.9 in Brighton, and 2.5 in Huddersfield; from measles, 2.9 in Blackburn, and 2.4 in Norwich; and from "fever," 2.1 in Newcastle-on-Tyne, and 1.2 in Birkenhead. The 11 fatal cases of scarlet fever in Hull raised the number recorded within the borough since the beginning of July last to 701. The 34 deaths from diphtheria included 14 in London, 6 in Glasgow, 5 in Edinburgh, and 4 in Portsmouth. Small-pox caused 21 more deaths in London and its suburban districts, one in Brighton, 2 in Salford, and one in Oldham.

As an instance of the serious waste of public funds going on in some of our medical charities and institutions may be mentioned the fact that, at the present time, there are 98 patients on board the small-pox hospital ship, *Atlas*, in the Thames, and 96 officials to attend them; worse still at Homerton Fever Hospital, where there are 48 patients and 70 officials. At Stockwell Fever Hospital there are 37 patients, and 57 officials to look after them. This matter was brought before the Metropolitan

Asylums Board at its meeting on Saturday last. Small-pox has been steadily decreasing in London for months past; and it appears to us monstrous that these large staffs are not reduced in like proportion.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

TYPHOID FEVER IN EDINBURGH.—It was reported on the 1st inst. to the Edinburgh Public Health Committee that the returns for the month of January showed 388 cases of infectious disease, including 167 of measles, 110 of scarlatina, 100 of typhoid, 6 of diphtheria, and 4 of typhus. Of cases of typhoid, 10 were in the New Town, 50 in the Old Town (of which 37 were in the St. Leonard's district), and 40 in the Southern Suburbs. On inquiry into these cases, it appeared that, with one or two exceptions, the houses in which they had occurred were in a satisfactory sanitary state. The milk used by most of the infected families in the Southern Suburbs and a few of those in St. Leonard's had been traced to one dairy, and the supply from this source had been stopped. The outbreak had gradually declined since the 19th ult., and no new cases had been reported for two days past.

THE LATE SIR ROBERT CHRISTISON.—We learn that there is good reason for believing that the immediate cause of Sir Robert's death was carcinoma of the omentum. For two months prior to his death Sir Robert had suffered from loss of appetite and other dyspeptic symptoms; he himself, we believe, however, first diagnosed the true nature and character of these. The funeral, on Wednesday, Feb. 1st, was largely attended, the *cortège* extending from one end of George Street to the other.

PRESENTATION OF BUSTS TO THE UNIVERSITY OF EDINBURGH.—At the last meeting of the Senatus Academicus of Edinburgh University, Principal Sir Alexander Grant presiding—two presentations were made to the University, one being that of a bust by Mr. Hutchison of the late Professor Sanders, M.D., and the other of a bust of the late Professor Hodgson, from the hand of the late Mr. Brodie. The busts have been placed in the library hall of the University.

THE ALLEGED DISAPPEARANCE OF A CORPSE FROM GREENOCK INFIRMARY.—A good deal of excitement and public indignation has been aroused during the past week by the disclosure of certain facts relative to the removal of a body, it is supposed for dissection purposes, from the Greenock Infirmary in November last. The official correspondence bearing on the case may be briefly summarised thus:—On Saturday, the 19th of November last, Hugh Sinclair, a man in the employment of the Caledonian Railway Company, and resident in Crescent Street, Greenock, died in the Infirmary from the consequences of a strain, which took the form of an inflammatory swelling behind one of the deceased's ears. Sinclair's wife was with him when he died, and immediately after the death she left for home to get linen to dress him for burial. On Monday, 21st November, she called at the Infirmary along with another woman to dress her husband's corpse, but in the lobby Drs. Whiteford and Dobie requested that they might be allowed to look at Sinclair's head, as they wished to examine into what they thought an unusual cause of death. This Mrs. Sinclair agreed to, although she now denies having given the doctors authority to cut the head. She called back to the Infirmary on the afternoon of the same day—21st November—to dress

the body of her husband, but on going into the mortuary there was only one dead body there, and it was not her husband's, but that of a fisherman named Logan. Since then Mrs. Sinclair has not seen the body of her husband, and she has, through a legal agent, called upon the Infirmary directors to deliver it up. The officials of the Infirmary say that the mistake occurred owing to erroneous identification by Logan's mother of Sinclair, as being the body of her son, and that, as a consequence, Sinclair was first interred as Logan. The directors say that the demand to exhume Sinclair's corpse from the common pauper ground would now be attended with much difficulty, as many burials have now taken place in the "parochial pit" since 21st November. The latest phase of the question is that the Infirmary directors and Mrs. Sinclair's law-agent are about to make a joint application to the Sheriff for the exhumation of the body of Sinclair, so that it may be dressed and interred in a purchased grave. It will therefore be seen that the authorities are on the horns of a dilemma.

FUNERAL OF SIR ROBERT CHRISTISON, BART., M.D., F.R.S.—The funeral of Sir Robert Christison, whose obituary we gave in our last, took place on Wednesday, and was one of the largest public funerals witnessed in Edinburgh for many years. At half-past one o'clock a private service was conducted in the house of the deceased by the Rev. Dr. Scott, of St. George's Church, at which there were present nearly 50 relatives and friends. Immediately on the conclusion of this service a short public service was held in St. George's Church, in which there were a large number of the representatives of public bodies and others. At its close the University Company of the Volunteers, and the students of the University and general public attending the funeral were formed into procession, and the *cortège* as it wended its way to the new Calton burying-ground, where the remains of the deceased were to be deposited in the family burying-ground, was of imposing length. No attempt at an oration was made over the grave, extreme simplicity in detail characterising the entire proceedings, and almost universal signs of mourning along the entire route, and by the assembled multitude were observed.

Correspondence.

HYPODERMIC INJECTION OF QUININE AS A PROPHYLACTIC IN CHOLERA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The suggestions which you did me the favour to publish in your issue of May 12th, 1880, on the above subject, having reached India, I had the honour to receive on Nov. 18th, 1881, from Dr. Cunningham, the surgeon-general with the Government of India, the following communication:—"That, owing to the danger attending the hypodermic injection of quinine in this climate (India) the practice has been prohibited. As the injection of the acid solution given in your formula would probably be attended with equal danger, and no certain advantage, as determined by experience, I regret that I do not feel justified in advising such a practice."

One cannot but admire the judicious caution of an officer placed in so responsible a position as is Dr. Cunningham, but I ask you to allow me to draw attention to a paper by Dr. Charteris, of Glasgow, in the *Lancet*, of Nov. 12, 1881, page 822, on the hypodermic injection of quinine in ague. Dr. Charteris used a solution of twenty grains of sulphate of quinine, and fifteen grains of tartaric acid in half an ounce of water. He writes that twenty minims of this solution were injected every two hours; (the number of such injec-

tions is not stated). "The injection caused no pain, and it was followed by no abscesses. I can testify as to the pain being nil, and to the absence of any inflammation . . . It seemed to have the effect of warding off the attack (ague) according to the man's statement."

As bearing on this subject it may be useful to quote Major Serpa Pinto, (a) who writes (Vol ii, p. 90):—"The following day I was much worse, being attacked with severe inflammation of the liver, for which I applied caustics of pulverized quinine." Again, at page 91 he writes:—"The pulverized caustics of quinine, and three grammes of that medicament, which I introduced into the system in three hypodermic injections at short intervals, calmed my feverish state, so that on the 10th (having injected on the 9th) I was able to rise, feeling considerably relieved." Again, at page 94, vol ii, he writes:—"The repeated hypodermic injections of quinine in strong doses had, against my expectations, nevertheless, overcome the fever, so that by six o'clock on the morning of the 12th I felt so much relieved that I determined to pursue my voyage."

I have not come across any remark, in Major Serpa Pinto's volumes of evils following the hypodermic injection, or the application to blistered surfaces of quinine.

I have injected hypodermically, quinine dissolved in dilute muriatic acid, without abscess or severe inflammation following, but in future I shall use Dr. Charteris' formula.

Yours, &c.,

WILLIAM H. PEARSE, M.D.

1 Alfred Place, Plymouth.

THE SALE OF POISONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The state of the law affecting the sale of poisons is at present attracting much attention in England, where the "Poisons Act"—faulty as it is—appears to be fairly carried out. Infractions of the Act, at least, lead to prosecution, when attention is called to them.

It is well that the public, as well as the medical profession, should be made aware that in Ireland this Act (33 and 34 Vic. cap. 26) is *absolutely a dead letter*. Has any one ever heard of a single prosecution having been instituted in Ireland under the Act? I have not. All over the country the most deadly poisons are sold by grocers, ironmongers, and other small traders, many or most of whom are not only ignorant of the dangerous nature of the commodities which they spread broadcast, but are even ignorant of the existence of such a chapter in the legislation of the country as a "Poisons Act." I have myself seen a package of potassium cyanide, containing half a pound, sold across the counter in the city of Dublin to a messenger boy, without any reference, or a single question asked, as to who the purchaser was. So far from complying with the necessary formalities prescribed by the Act in the way of entry in book, introduction, &c., the parcel had not even the word "Poison" marked upon it.

Cases such as this have been frequently brought under the notice of the Council of the Pharmaceutical Society, who, I regret to say, are powerless in the matter.

Under the Pharmacy Act (Ireland), (38 and 39 Vic., cap. 57), which constitutes our Society, and grants to our licentiates in the future the sole privilege of selling the scheduled poisons, the Legislature, with a due regard to vested interests (which even at so recent a date were considered to be entitled to some respect), reserved to all persons (sec. 31), no matter how ignorant, who were at the time engaged in the sale of poisons, the right to continue their dangerous trade. No machinery was provided for registration of such persons, nor can any check be imposed by our Council, who are supposed to have some responsibility in the matter, and who are most anxious to interpose between the public and a very alarming danger.

Two years ago, a deputation from the Council of the Pharmaceutical Society waited on one of the permanent officials of the Irish office, by whom they were favourably received, and upon whom they impressed their views. These were, that powers should be given to our Council, by a Short Act, to compel all persons whose vested rights were preserved by the Pharmacy Act to come in before a certain date, or register their names,

(a) "How I crossed Africa." By Major Serpa Pinto: 1881.

giving satisfactory proof that they were at the passing of the Act engaged in the sale of poisons. This would no doubt authorise many ignorant persons to engage in a dangerous trade, but there would be some feeling of responsibility arising out of the fact of being registered; there would be a desire to prevent other persons totally unauthorised from engaging in the traffic; there would be some observance of the requirements of the Act; and above all, there would be some finality in the arrangement; and at some time the sale of poisons would be confined to those who had proved by examination their fitness to deal with such things. Any proceedings taken now are certain to be met by the defence that the person prosecuted was within his rights in selling poisons, and it is unnecessary to say how difficult it would be to obtain a conviction in this country.

Nothing has been done by Government since to give effect to our suggestions, nor will anything be done until some great calamity takes place, when perhaps attention may be called to the subject.

I have no doubt that the matter, if ventilated through your columns, will receive the attention of the medical profession, and if pressed by them, may lead to some effectual amendment in the law.

I am, Sir, yours, &c.,

J. E. BRUNNER, M.D.

68 Grafton Street, Dublin,
Jan. 26, 1882.

MODIFIED AND NATURAL SMALL-POX.

THE following correspondence has been forwarded to us for publication by Dr. Buchanan:—

A LETTER ADDRESSED TO P. A. TAYLOR, Esq., M.P.

DEAR SIR,—I feel obliged by your courtesy in sending me your pamphlet.

I have read it with deep interest, but at the same time with profound astonishment, that you should entertain and make public the doctrine therein set forth.

You are obviously an expert logician, and if you had accurate data before you, would, I believe, rarely come to a wrong conclusion. Unfortunately, in the question which you raise in your pamphlet, only one half of the data are known to you, and of the other half you seem not to have the most remote conception.

You are, perhaps, wisely distrustful of the statements of men whom you believe to have a pecuniary or other personal interest in the statements they make. Will you accept the testimony of an octogenarian, who has no interest to serve but the interest of truth, and who has, I believe, seen as much of the *natural small-pox* as any man now living?

I presume you understand that by *natural small-pox* we understand the disease as it occurs in persons who have not been protected, either by vaccination or by inoculation with the matter of small-pox, and that we use the term in contradistinction to *modified small-pox*, the form which the disease assumes in persons who have been protected in either of the above ways.

Now it is only this last form of the disease that you have ever seen, and of the former you have no idea whatsoever. Could I but reverse the car of Time, and carry you down with me to Glasgow in the year 1819-20, you would in the course of a few hours understand the whole natural history of small-pox.

There is a severe epidemic of small-pox raging in the city. The inhabitants have been all protected by the wise regulations of the Faculty of Physicians and Surgeons. The men above 20 or thereabout have all been inoculated with small-pox matter, or have had the natural disease, (a) and of those not one took ill, so much more thorough is the protection given by having had small-pox than that which vaccination confers.

Among the young people who had been vaccinated a brisk epidemic prevails. There is high fever, with an eruption of papules with a clear liquid on the summit, which gradually blackens, or in more severe cases passes into purulent matter.

(a) I believe I was the last person in Glasgow who underwent inoculation for small-pox, our family physician, Dr. Anderson, keeping to the practice of Lady Wortley Montague, after all his colleagues had become converts to Jenner,

The disease was over in six or eight days, and there was not a single death so far as I knew.

But I have now to draw a more melancholy picture, when I direct your attention to a third class of the inhabitants—strangers who had come to Glasgow in quest of employment chiefly from the north and north-west Highlands. These poor people were for the most part quite unprotected, and took the disease in its most virulent form. They were carried to wards appropriated to them in the Fever Hospital of the Glasgow Royal Infirmary, which was then in the back wing of the old house.

As you enter the ward you are assailed by an acrid stench, *sui generis*, which compels you at once to shut your mouth and compress your nostrils.

The man you see in this bed has just been brought in. He has the confluent small-pox, the worst form of the disease. He is in a state of such extreme prostration, that in whatever position he is laid, he is quite unable to change it; but he is in the hands of kind and intelligent nurses. His face is swollen to double its natural size, and covered with large irregular blebs filled with putrescent greyish matter. The patient in the next bed lies on his back, encased in a mask of brownish-black scabs. The next one is farther on, sitting up picking the scabs from his bleeding face and skin. We need not go farther, for the other cases are quite similar. The mortality varied from one in three to one in four and upward, according to the period of the epidemic and other circumstances. I trust your eyes are now opened, and that you see the fallacies in which you have involved yourself and your readers.

The great glory of the immortal Jenner does not consist in his having extirpated small-pox, which is as ripe as ever, but in his having converted the most loathsome and fatal affection with which God in his wrath ever afflicted the human race into a trifling or mild disease.

Your attempt in your pamphlet to tear the laurels from the honoured brow of Jenner, and the direct tendency of the pamphlet is to bring back among us the natural small-pox—an open enemy to the human race would attempt the same thing. But I willingly and fully acquit you from all malevolent intent, because you speak in ignorance. But it is surely not wise in you to oppose the whole Medical Faculty on their own field, and in a most important practical question; besides misleading your constituents, and others into paths, where you yourself are groping your way in the most profound darkness. My advice to you, therefore, is that you should commit to the flames the numerous copies of your pamphlet still on your hands.

With much respect for your high position as a Member of the Commons' House of Parliament,

I remain, yours sincerely,

186 Bath Street, Glasgow,
Dec. 28, 1881.

ANDREW BUCHANAN.

P. A. Taylor, Esq., M.P.

P.S.—I intend publishing this letter, and should you honour me with a reply, I shall, with your permission, publish it at the same time.

MR. P. A. TAYLOR'S REPLY TO DR. BUCHANAN.

DEAR SIR,—I beg to thank you for the courtesy of your observations on my letter to Dr. Carpenter, as also for your offer to print my reply with your own letter.

My answer will be very short. You declare that "The great glory of Jenner is not in having extirpated small-pox, because it is as ripe as ever, but in having turned it into a mild disease."

If you will do me the favour to read my letter more carefully, you will perceive that official statistics are dead against your theory, and prove beyond all doubt that the ratio of deaths to cases, in small-pox, is quite as great in the *protected* England of the 19th century as in the *unprotected* era of the 18th.

I am, dear Sir, yours faithfully,

P. A. TAYLOR.

22 Marine Parade, Brighton,
Jan. 7, 1882.

A. Buchanan, Esq., M.D., LL.D., &c.

DR. BUCHANAN'S REPLY TO MR. TAYLOR.

DEAR SIR,—I have read over your pamphlet again, attending particularly to the statistics, as you ask me to do. The

most interesting to me are those in which you compare the deaths in the small-pox hospitals in reference to the number of cases in the vaccinated and the unvaccinated, and find it to be *eighteen* in the one and *nineteen* in the other, omitting fractions. Now I have no doubt this is a true ratio, for it accords with the experience of every physician, that if vaccination fails to impart its preventive efficacy, the disease assumes very much the form of *natural small-pox*. But when you infer that a saving of life to the extent of one per cent. is all that is gained by vaccination, you forget that it is only the worst of vaccinated cases that are sent to the hospital, and that for one such case there are at least fifty in which the disease was a mere trifle. Among the lower ranks the disease very frequently is never discovered—a man feels quite well, and takes his food, and is not disturbed by a few pimples on his face. The thing is only discovered when some person gifted with the *tactus eruditus* looks perhaps on two pimples on the back of the neck, or on the brow, and pronounces them to be genuine variolous pustules; he follows this up with the proposal to send the patient to the Small-pox Hospital, to the indignation of the patient and his friends; and hence the systematic concealment of small-pox among the lower orders. The sanitary authorities, in such cases, should be quite satisfied with confining the patient to his own home, as is done and allowed in richer families; for there should never be one law for the rich and another for the poor.

It is quite clear from what I have stated above, that no trustworthy report of cases of *modified small-pox* can ever be expected from the sanitary authorities. But the ratio of deaths from *small-pox after vaccination* to the number of cases can be readily determined by any medical man who keeps an accurate record of his cases. I cannot pretend to have done so, but speaking from memory, I would say that not more than one in fifty cases would have been a fit patient for an hospital; but to be fairly within the mark, let us say 25; that is, one case in 25, or 4 in 100, are sent to the hospital. Now of these there die 18 per cent. Combining these ratios, the result is that the death-rate from modified small-pox in 100 cases is 0.22, that is, one-third of a per cent., or one death in three hundred. In my own practice I have seen very bad cases, but never a single death. This result accords with the testimony of my brother.

Quite recently an attack of small-pox took place among my grand-children; one of the children took it, but whence it came from is a mystery. The house is quite isolated, and there was no small-pox in the neighbourhood. Ten days afterwards, the usual period of incubation, other six children took it—all but the baby, who had providentially been vaccinated a short time before. None of the patients lay in bed for a single day. They had good spirits and good appetites, and were all quite well again in eight or ten days. How thankful should we be to Almighty God, who has given to us and to our children a mild and painless disease in the place of the loathsome and fatal *natural small-pox*!

I am, dear Sir, yours sincerely,

186 Bath Street, Glasgow,
Jan. 11, 1882.

A. BUCHANAN.

P. A. Taylor, Esq., M.P.

Obituary.

MR. OWEN, OF PLYMOUTH.

WE regret to announce the death of Mr. Thomas Edward Owen, surgeon, which took place last week at his residence, Locker Street, Plymouth. The deceased gentleman had been in a delicate state of health for some time past, but had been able to attend to his professional duties. On Wednesday evening he was taken ill, and removed to his residence. He vomited quantities of blood towards midnight, and two hours later passed away as if in a quiet sleep. Mr. Owen was forty-four years of age, and formerly practised at Totnes, but for the past seven or eight years has resided in Plymouth. He was M.R.C.S., England; L.S.A. and L.M. (Dublin); formerly house surgeon at the Rotunda Hospital, Dublin, and the Royal Free Hospital, London.

Literature.

KOUMISS, OR FERMENTED MARE'S MILK. (a)

THE reader of Dr. Carrick's work on "Koumiss, or Fermented Mare's Milk" will find much to interest and instruct him. We learn that the first time koumiss is mentioned by name is in the "Ipatof Chronicles" of the 12th century, where it is told how Prince Igor Seversky was taken prisoner by a nomad tribe of Mongolians dwelling in the south of Russia, and the captors got so drunk upon koumiss that they allowed their prisoner to escape; from which we are to conclude that koumiss was stronger, or people's heads were weaker, then than now.

William de Rubruquis, a French friar, who travelled in Tartary in 1254, says that koumiss makes the inside feel very comfortable and it intoxicates weak heads. If this be so, the individual who finds that he cannot drink koumiss without some degree of intoxication resulting, must infer that his head is a weak one, and will not stand alcohol, even when blended with such a wholesome liquor as milk.

Chapter III., treating of the chemical changes which milk undergoes during fermentation is worth careful perusal, for the author has carefully worked out the chemistry of the process according to present knowledge. The chemical change effected in milk as it becomes koumiss appears to consist in the sugar (lactine) undergoing the vinous as well as the lactic fermentation; in the greater part of the casein becoming separated from, while a small part is dissolved in, the whey; and in a slight decrease in the amount of albumen and lacto-protein, at the expense of which the ferments feed. When milk is fermented by the aid of yeast at a temperature of 80° to 90° F., lactic acid very speedily develops, but it is not until the lapse of five hours that a true vinous odour can be detected in the milk. Brisk agitation of the milk and exposure to the air powerfully aid the vinous fermentation, and fulfil also the important indication of preventing the lactic acid, formed early in the process, from passing into the noxious butyric acid. Furthermore, to prevent butyric acid developing, the milk must not be too rich in fat. Mare's milk being rich in lactine and comparatively poor in butter is well adapted for the preparation of koumiss.

We cannot pursue further the chemistry of koumiss-making, but would draw the attention of the reader to the appendix on the fermenting of cow's milk. Cow's milk koumiss appears, from the remarks of Dr. Carrick, at page 266, to have been prejudiced in his estimation by the over-laudation bestowed upon it by some of its supporters. We believe that if Dr. Carrick would follow the rule that we ourselves endeavour to pursue when seeking to estimate the value of any new remedy, and which is entirely to discard all "testimonial" and then to try the preparation fairly on patients, he would find that well-made cow milk koumiss has earned for itself some claim to credit as a useful dietetic agent in cases of weakness and irritability of stomach.

The Tartars, it seems, do use cow's milk for making koumiss when mare's milk fails, and Dr. Polubensky, who had derived much benefit personally from the use of koumiss made from mare's milk found, during many a winter, that fermented cow's milk very well replaced the genuine article in his diet list. Dr. Polubensky's directions for preparing koumiss from cow's milk are fully detailed, and can be followed out easily enough.

Lastly, the effect of living at Samara, or on the Steppes, and drinking koumiss appears to have a wonderful effect on consumptive invalids. Prof. P., a phthisical gentleman, went, by the advice of Dr. Carrick, to Samara for the koumiss cure. In six weeks the professor had grown into a round-faced, fresh-coloured, plump individual, whom Dr. Carrick failed to recognise. Five bottles of koumiss daily and the Steppe air had increased this man's weight by 14½ pounds. Increase of weight in cases of well-developed

(a) "Koumiss, or Fermented Mare's Milk, and its Uses in the Treatment and Cure of Pulmonary Consumption and other Wasting Diseases." With an Appendix on the methods of Fermenting Cow's Milk. By George L. Carrick, M.D., L.R.C.S.E., L.R.C.P.E.; Physician to the British Embassy at St. Petersburg; Secretary and ex-President of the St. Petersburg Physicians' Society, &c., &c. Pp. 294. London and Edinburgh: Blackwood & Sons.

phthisis has been observed by all who have visited the koumiss cure establishments of Oranbourg and Samara.

We would wish to awaken interest in this book of Dr. Carrick's; it is written in a thoroughly professional spirit, and, before sitting down to write, the author made six different journeys to the Steppes to see the cure at work there in the establishments of Dr. Postnikof and others. Before 1858, the year in which the establishment of Postnikof started, the number of patients who left their homes to undergo the mare's milk cure could be counted by the dozen; now, according to Dr. Shermazanof, there are nearly 1,500 patients treated annually in the several koumiss establishments in the vicinity of Samara alone.

It is well known how cow milk koumiss has already obtained a good footing in this country under the auspices of Dr. Jagielski, and we can only hope that an agent of evident promise may obtain a fair and extended trial.

TROPICAL DYSENTERY AND CHRONIC DIARRHOEA. (a)

In his work on Tropical Diseases, Sir Joseph Fayrer has brought together so much information, valuable especially to the medical officer in India, that it becomes somewhat difficult, out of so much that is valuable, to select even a few points whereon to comment. On the subject of Dysentery he gives (p. 10) a series of tables showing the ratios of sickness and mortality by the disease in 1878 in each of the three presidencies. According to that table the ratios per 1,000 mean strength were:—In Bengal 39.7 admissions; in Madras 93.9; Bombay 35.3; India generally 49.3. The rates of mortality per 100 cases treated of the same disease on the same occasion were respectively—3.80, 3.25, 3.14, and 3.52. Thus it appears that, whereas in Bengal the liability to attack was somewhat greater than in Bombay, and very much less than in Madras, the death-rate among those attacked was considerably greater than in either of the smaller Presidencies. It would be interesting to compare figures thus given with statistics of years long past. For example, in 1812, viz., the first year for which statistics are available, among the British troops in Bengal the ratio per 1,000 strength admitted on account of dysentery was 281; the ratio of deaths per 100 treated for that disease was 8. Those were times when much severe work, including exposure of our troops in India, was performed by soldiers; when in barracks they were crowded together; when rations consisted for the most part of salted food and spirits; and when the type of disease generally among them was very much more severe than it is at the present time; and yet, while the rate of prevalence was seven times greater than it was in 1878, the rate of mortality in the severer form was little over twice that of the later date. Hence it follows that the rate of mortality as compared to severity was absolutely less at that early date than it now is. As to the causes of the disease, those most commonly in operation are enumerated at page 30, viz.—“vicissitudes of climate; exposure to cold and heat; sudden alternations of temperature; exposure to damp winds; the ill-effects of moisture of the rainy and drying-up season in September and October; exposure of the body, especially the abdomen, during sleep, or when perspiring; the sudden laying aside of flannel body-clothes, and so on.” He alludes (p. 43) to the greater prevalence of the disease in India than in other climates; he then discusses the pathology and morbid anatomy of the disease, quoting the observations on these points made by Drs. Goodeve, Chevera, and other eminent authorities on Indian diseases. In discussing the treatment of dysentery (p. 6) the author refers to the administration of ipecacuanha in large doses, in place of the system of small doses, as had previously been the case from the year 1658, when, under the name of the radix dysenterica, the drug was first introduced into England from Mexico. That method has been a good deal followed in India since 1858, when a paper on the subject appeared in the *Lancet*. Unfortunately, the Army Medical Blue Book does not furnish the means of instituting a comparison of mortality by particular diseases throughout a series of years. From information available, however, we learn that in the Bengal Presidency, in the year

from 1st April, 1855, to 31st March, 1856, &c., prior to the introduction of large doses, the admissions on account of dysentery were 1,114; the deaths 98; equal to a ratio of 8.7 per 100; that in 1868, when the treatment by large doses of ipecacuanha was in the first flush of fashion, the admissions, 1,867 in number, gave 104 deaths; equal to a ratio per cent. of 5.5. Thus, no doubt, statistics show a considerably diminished death-rate after the date when the new system of treatment was adopted. But does it follow that this decrease was in consequence of that new method? By no means. From improvements in the conditions under which the soldier lived, brought about as a result of the Royal Commission regarding the health of the troops in the Crimea, the prevailing type of this disease, as of others affecting the soldier, became diminished; then also, in consequence of the influx of newly-arrived regiments and soldiers to take the place of those that had served in the Mutiny, the mortality as shown by figures occurred by first attacks, rather than in persons who had suffered several, as had previously been the case. But the fact is, statistical figures by themselves are by no means infallible or safe guides with regard to medical matters, involving, as these do, so many circumstances of which arithmetical symbols can take no note. In cases of inflammatory dysentery, ipecacuanha in large doses may, and does moderate the vascular condition. But so also do the application of leeches, fomentations, warm-water enemata by means of the long tube, as used by O'Bierne many years ago, and the employment of calomel and opium internally. In cases of hemorrhagic, scorbutic, or purely malarial dysentery, on the contrary, the administration of ipecacuanha in large doses proves directly pernicious; while, in any case, the extreme nausea and discomfort in other respects which follow its administration induce many medical officers to employ less unpleasant remedies. And this they do with equally good effect.

Then follows a chapter on Bael fruit as employed in the treatment of dysentery. *Aegle marmelos*, the tree which yields the wood-apple, Bael, or Naraidu as the fruit is respectively called by English residents in India, and by natives of Bengal and Madras, belongs to the natural order Aurantiaceae. Probably on account of its medicinal qualities it is cultivated in the vicinity of Hindoo temples, and on account of its ternate leaves is considered typical of the Trinity of Brahmin mythology, as the Oxalis and Trifolium severally are to the Trinity of our own faith. With regard to the actual properties of the fruit in the treatment of dysentery, opinions differ. In cases of chronic diarrhoea the carminative properties of the pulp render it a decidedly pleasant medicine to take. In Calcutta an agreeable sherbet prepared from it is much used both by natives and by Europeans during the rainy season as a prophylactic against bowel complaints generally; in Madras, however, it does not appear to be so. In the Straits of Malacca the rind of the *Garcinia mangostana* is made use of both as a prophylactic against and a remedy in dysentery. In China the *Ailanthus glandulosa* is similarly used, and it is stated with such success that the natives of “the central Flowery Land” consider their own method of treating dysentery to be more successful than that adopted by European physicians.

Sir Joseph Fayrer adds chapters on Liver Abscess; on Malarial Cachexia; Beri Beri; Bronchocele; Elephantiasis; on the *Filaria sanguinis hominis* in relation to Endemic Diseases; on Sunstroke; Dengue; Health of Children in India; Preservation of Health; and Rainfall in relation to Health and Disease.

OBSERVATIONS ON THE CÆSAREAN SECTION, CRANIOTOMY, AND OTHER OBSTETRIC OPERATIONS, WITH CASES. (a)

THE publication of this work on a rather difficult but important subject will be a matter of much satisfaction to all obstetric practitioners, whether specialist or otherwise, from the fact that it presents an able résumé of the whole matter. Where opinions are so diametrically opposed as on the

(a) “Tropical Dysentery and Chronic Diarrhoea.” By Sir Joseph Fayrer, K.C.S.I., &c., &c. London: J. and A. Churchill, 1881.

(a) “Observations on the Cæsarean Section, Craniotomy, and other Obstetric Operations, with Cases.” By Thomas Radford, M.D., F.R.C.P. Edin. F.R.C.S., Eng., &c.; Hon. Consulting Physician to St. Mary's Hospital, and the Manchester and Salford Lying-in Hospital. Second Edition. London: J. and A. Churchill.

justifiability of this operation, it is hardly for us to express ours, further than to say that, with all Dr. Radford has added the case remains pretty much in the stage of "not proven." The whole subject is very carefully handled, and the arguments made use of are forcibly, if not altogether convincingly, put. To the impartial reader it is, however, evident that the work is that of one who believes in his subject almost enthusiastically, and therefore, he cannot help noting the strong bias that prevails throughout the book. That this is a decided advantage is indisputable, as it holds the subject up clearly from a decided point, that is to say, the author has here laid before us all that can be said in favour of the operation. When an obstetric practitioner of more than 40 years' standing expresses an opinion founded on experience, we listen with respect and carefully weigh his reasons. The work is divided into two parts, the first, dealing more with the discussion of the operation and its necessity, the second being more practical, and giving cases. In Chapter I. the necessity of Cæsarean section as an obstetric operation is dwelt upon fully, and the reasons for having recourse to it at all, enumerated, and the various causes rendering delivery *per vias naturales* impossible, noticed. In Chapter II. the statistics of Cæsarean section are alluded to; this is followed by a glance at the various causes of maternal and infantile mortality, the causes of which are very fully discussed, with regard to the former especially. One point justly dwelt upon is the extra chance of recovery in cases when early performance of any obstetric operation is had recourse to, instead of waiting till the whole physical powers are exhausted or depressed.

One of the most important chapters is that devoted to the performance of the operation. In these days when we find the peritoneal cavity continually freely opened and exposed, with ultimate good recovery, most of the dread and uncertainty formerly surrounding the performance of such serious operations as Cæsarean section, have been dispelled, and we are compelled to look to other causes for the high mortality, than either the susceptibility of the parts concerned, or the condition of the patient at the time. To the man who finds himself in a position requiring the performance of this or similar operations, the minute directions given here are valuable, and for the first time, laid before us in a special form.

The author lays stress upon ascertaining exactly the position of the uterus before making any incision, and also what change of form may have taken place from abnormal shape or distortion of pelvic cavity. For reasons which he gives, a lateral incision through the uterus is chosen, before making which it is desirable not only to learn the position and shape of the organ, but also the location of the placenta, so as to avoid wounding it if possible. In Chapter IV. he says, "Before the incision is made it is of the utmost consequence to raise the deflected uterus up, or else the fundal tissue which abounds with large anastomosing vessels, must unavoidably be divided. Neglect of this caution has, no doubt, led to hæmorrhage which happened in some of the cases. A division of the structure of the upper part of the fundus must certainly interfere with the regular or efficient contraction of the organ, and thereby produce a gaping character of the wound."

In the remaining chapters of the first part, the alternative operative measures for effecting delivery in cases of contracted or distorted pelvis are fully discussed and weighed *pro and con*. The employment of the long forceps—turning in cases of slight distortion—the induction of premature labours—the induction of abortion at an early period of gestation—when it is evident that, by no human means, short of Cæsarean section can anything above a half-developed child be delivered through the pelvic opening.

Ovariectomy, in itself a moot point, and evoking much discrepancy of opinion is fairly and well discussed, adverse opinions being freely quoted and debated, the relative value of the two operations being fairly laid before the judgment of the reader.

In his concluding chapters Dr. Radford enters freely into the matter of the relative value of maternal and infantile life. Stating all that can be said on the matter whether ethically as a question of morals, or maternally, as a cause of stern necessity, when life has to be saved.

The second part of the work is devoted to the concentration of the references to all ascertained cases of this operation, in the hope that it may prove valuable to all "who are desirous to analyse and compute the risks and dangers of it, in com-

parison with the results of those alternate operations which are recommended to supersede its performance."

In this part every circumstance bearing upon the case in any way is considered and tabulated. The general connection with the result estimated. The points more especially noted are the number and kind of previous labours, the mode of delivery, the state of the os uteri, the situation of the placenta, the line of incision, the constitutional state, the use of anæsthetics, the reputed cause of death, and the result of any post-mortem examinations. In the cases given, all such practical matters as the occurrence of hæmorrhage or peritonitis, the sutures used, the occurrence of exhaustion, &c., are, as far as possible, given.

A most valuable feature in the work is the appendix of tables giving some account of every known case in this country, 131 in all. Comprising year, name and address of patient, by whom related, operator, cause of difficulty, duration of labour, and result. The only omission in these tables which might be rectified, would be to state if possible the number of the pregnancies in each case.

In conclusion, we have only to say that, this is the most complete monograph we have on the subject, and therefore doubt not its good reception by obstetricians.

PASS LISTS.

Royal College of Physicians of London.—The following candidates having passed the required examinations, were admitted members, January 26, 1882:—

- Bevor, Charles Edward, M.D. London, 129 Harley Street, W.
- Bradshaw, Alexander Frederick, Devonport.

Royal College of Surgeons of England.—At meetings of the Court of Examiners on January 19th, 20th, and 23rd, the following gentlemen, having passed the required examination for the diploma, were duly admitted Members of the College:—

- Williams, Walter Treloing.

Army Medical Service.—The following is a list of Surgeons on Probation in the Medical Department of the British Army who were successful at both the London and Netley examinations, February 6, 1882:—

IN M. Reid	No. of Marks	J. W. Jerome	No. of Marks
W. H. P. Lewis	2,325	W. W. Pike	1,675
W. Dick	2,229	M. E. Fitzgerald	1,670
*F. J. Jencken	2,141	L. H. Trueitt	1,670
F. H. Treherne	2,105	J. M. Irwin	1,665
S. F. Loughheed	2,100	F. J. Nealon	1,650
J. C. Haslett	2,075	E. O. Wight	1,640
H. J. Barratt	2,065	W. A. Morris	1,625
H. E. R. James	2,025	F. H. M. Burton	1,610
H. O. Trevor	1,990	J. Heath	1,605
A. F. Russell	1,985	C. H. Nichol	1,605
R. J. Fayle	1,971		

† Gained the Martin Memorial Gold Medal. * Gained the Montefiore Second Prize.

Indian Medical Service.—The following is a list of Surgeons on Probation in Her Majesty's Indian Medical Service who were successful at both the London and Netley examinations, 6th February, 1882:—

	No. of Marks		No. of Marks
† L. T. Young	5,217	E. B. Roe	4,485
**J. B. Gibbons	5,205	John Smyth	4,460
* G. J. Shand	5,010	H. Greany	4,090
D. St. J. Grant	4,828	E. P. Youngerman	3,980
D. G. Crawford	4,640	J. Kernan	3,980

† Gained the Herbert Prize, the Martin Memorial Silver Medal, and the Parkes Memorial Bronze Medal. ** Gained the Montefiore Medal. * Gained the Prize in Pathology.

NOTICES TO CORRESPONDENTS.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

DR. MACILROY (Portglenone).—1. Neale's Digest is a most exhaustive and valuable catalogue of papers published in medical periodicals, but nothing more. It contains nothing about treatment. 2. The new scale of fees has been issued behind the back of the Irish Medical Association and kept studiously secret from them. We very much wish for a copy of it, if you could get it.

FEES FOR EXAMINATION OF DANGEROUS LUNATICS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—A reply to the following questions in the next issue of your valuable journal would much oblige,

Yours truly,
L. E.

The family medical attendant (who is not a dispensary doctor) of Miss D. is called upon to visit her. He considers her a dangerous lunatic. Are the magistrates empowered and legally compelled to call in the district medical officer (Poor-law) to examine her and sign the certificate for her removal to the district asylum and ask the friends of the patient to pay the doctor his fee?

A young lad who is subject to bronchial attacks during the spring months, his present residence is low and damp, and exposed to east winds, is of a lymphatic temperament, and wishes to try a change of air during the months of February and March—a dry, bracing climate agrees best with him. Would Rostrough (co. Down) suit him, or would you recommend one of the English or Scotch health resorts? and, if so, where?

[1. The 10th clause of the Act 30 and 31 Vic., cap. 118, which covers this matter, is as follows:—"10. Whenever any person shall be brought before any two Justices and it shall be proved to their satisfaction that such person was discovered and apprehended under circumstances denoting a derangement of mind, and a purpose of committing some crime for which, if committed, such person would be liable to be indicted, the said Justices shall call to their assistance the medical officer, or, if there be more than one, the nearest available medical officer of the dispensary district in which they shall be at the time, and if there shall not be any such medical officer available, then the nearest available medical officer of any neighbouring dispensary district, who shall examine such person." By a subsequent Act the Justices may order payment of a fee by the guardians, but, of course, if the friends of the patient have already paid, the magistrate will not give such order. This law applies only to dangerous lunatics brought up by the police. As regards the harmless insane, the friends must pay, or no one, and any medical practitioner may certify. 2. We request our readers to answer this.—Ed.]

DR. CROFT.—Thanks for the interesting little pamphlet. Mr. On Lee evidently intends to retaliate. He thinks that as Englishmen have formerly made money in China it is high time to turn about and see what a Chinaman can do in England. He flies at high game, for few of his order would advertise their fee at a guinea.

DR. SHAND (Glasgow).—We hope to find room for your communication "On Vaccino-Tuberculosis and Vaccino-Syphilis" in our next number.

AN OLD SUBSCRIBER (Galway).—The health resorts most suitable for cases mentioned in your note are all on the South Coast, viz., Hastings, Ventnor, Bournemouth, and Torquay.

MR. T. B. CAIR (Leeds).—Received as we were at press.

L. E.—We don't know to what your note refers; please explain.

COST OF THE L.R.C.S.I.—A correspondent writes: Would you please answer the following queries through your Journal, and oblige:—

1. What time elapses from the time a student passes his preliminary examination until he gets his L.R.C.S.I. & L.M. in a case where he is going in for those two degrees only? 2. Is there any book published as a guide to medical students? 3. What is the amount of fees for hospital lectures (approximately) for the above degrees?

[1. Nominally four years, really two years and nine months. 2. "Students' Number" of *Medical Press*, 3 Molesworth Street, price 6d. 3. Lectures, about £20; hospital, £37 16s.; diploma fees, £26 5s.; grinding, extra.—Ed.]

MEETINGS OF THE SOCIETIES.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—This (Wednesday) afternoon, at 4 o'clock. Prof. W. K. Parker, "On the Morphology of the Mammalian Skull."

HUNTERIAN SOCIETY.—This evening, at 7.30 o'clock. Annual General Meeting for the Election of Officers.—8 o'clock. The Hunterian Oration will be delivered by Dr. Robert Fowler, in the Theatre of the London Institution.

ROYAL MICROSCOPICAL SOCIETY.—This evening, at 8 o'clock. Annual Meeting for Election of Officers and Council.

EDINBURGH OBSTETRICAL SOCIETY.—To-day (Wednesday), at 8 p.m., "A Case of Exomphalos, where the Intestines of the Fœtus presented during Labour," with Specimen.—"Fibromyxoma Duplex Ovariorum. (From the clinique of Prof. Simpson, St. Petersburgh.) By Dr. Popow, Pensa. Communicated by Dr. J. Matthews Duncan, London.—"Clinical and Experimental Observations on the Bladder during Parturition," by Dr. J. Halliday Croom.—"On some

Points in the Physics of the Rectum and Bladder," by Dr. D. Berry Hart.

ABERNETHIAN SOCIETY (St. Bartholomew's Hospital).—Thursday, Feb. 9th, Dr. Stowers, "On Skin Diseases in Relation to Syphilis."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Friday, Feb. 10th, at 4 p.m., Prof. W. K. Parker, "On the Morphology of the Mammalian Skull."

ROYAL INSTITUTION.—Friday, Feb. 10th, at 8 p.m., Prof. Frankland, "On the Climate of Town and Country."

CLINICAL SOCIETY OF LONDON.—Friday, Feb. 10th, at 8.30 p.m., Mr. Knowlsey Thornton, "On a Case of Threatened Suppression of Urine after Ovariectomy; arms packed in cold wet towels; recovery."—Mr. Balmanno Squire, "On a Case of Erythema Iris."—Dr. D. W. Finlay, "On a Case of Aneurism of Ascending Aorta" (patient will be shown).—Mr. R. J. Godlee, "On a Case in which a piece of Grass swallowed by a Child made its exit in an Intercostal Space."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Monday, Feb. 13th, at 4 p.m., Prof. Parker, "On the Morphology of the Mammalian Skull."

ROYAL INSTITUTION.—Tuesday, Feb. 14th, at 3 p.m., Prof. John G. McKendrick, "On the Mechanism of the Senses."

Vacancies.

Bodmin Union, Cornwall.—District Medical Officer. Salary, £32 2s. per annum. Applications to be sent to the Clerk to the Guardians on or before Feb. 23.

Bristol General Hospital.—Physician's Assistant. Salary, £50, with board. Applications to be addressed to the Secretary on or before Feb. 18.

Drogheda Union, Monasterboice Dispensary.—Medical Officer. Salary, £110, and £20 as Medical Officer of Health. Election, Feb. 21.

Glennasmaddy Union, Williamstown Dispensary.—Medical Officer. Salary, £130, and £25 as Medical Officer of Health. Election, Feb. 17.

Liverpool Eye and Ear Infirmary.—House Surgeon. Salary, £80, with board. Applications to the Hon. Sec. not later than Feb. 10.

Radcliffe Infirmary, Oxford.—Junior Resident Medical Officer. Salary, £80, with board. Applications to be forwarded to the Secretary not later than Feb. 22.

Rotherham Hospital.—Resident House Surgeon. Salary, £100, with board. Applications must be sent to the Hon. Sec. on or before Feb. 23.

Appointments.

BALLARD, P., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Fourth District of the West Ashford Union.

BARTON, J., Medical Officer to the South City Dispensary, Dublin.

CARRINGTON-SYKES, M., L.R.C.P.Lond., M.R.C.S., House Surgeon to the Beckett Hospital and Dispensary, Barnsley, Yorks.

DWYER, Dr. J., Medical Superintendent of the District Lunatic Asylum, Mullingar.

EVANS, W. G., L.R.C.P.Ed., L.R.C.S.I., Medical Officer to the Second District of the Frome Union.

HARDIN, W., L.K.Q.C.P.I., F.R.C.S.I., Medical Officer to the West Drayton District of the Uxbridge Union.

KNIGHT, W., M.B.C.S., L.R.C.P.Ed., Surgeon to the Western General Dispensary, Marylebone.

MATTHEWS, W. C., M.B.C.S.Eng., Medical Officer of Health for the Township of Gorton, near Manchester.

RYAN, W. H., L.K.Q.C.P.I., L.R.C.S.I., Medical Officer to the Seventh District of the Newport Fagnall Union.

STIVEN, E. W. F., M.D., L.R.C.S.Ed., Medical Officer to the Harrow District of the Hendon Union.

WALLACE, A. C., M.R.C.S., L.R.C.P.Lond., House Surgeon to the Idacolin County Hospital.

WALKER, E. B. S., M.B., Junior Assistant Medical Officer to the Sussex County Asylum.

WILLIS, J. M.D., M.R.C.P., a Physician to the Infirmary for Consumption, Merrigat Street, Cavendish Square, W.

Births.

BLAKE.—Jan. 29, at Dene Side, Great Yarmouth, the wife of Henry Blake, M.B., of a son.

FIRLAY.—Feb. 3, at 21 Montagu Street, Portman Square, London, the wife of D. W. Finlay, M.D., of a son.

GILCHRIST.—Feb. 1, at 11 Park Village, Regent's Park, London, the wife of Campbell Gilchrist, M.B., of a daughter.

Marriages.

GUNN—BURKE.—Feb. 1, at the pro-Cathedral, Marlborough Street, Dublin, Christopher Gunn, M.D., to Mary Catherine, only surviving child of John Burke, 14 Upper Sackville Street, Dublin.

Deaths.

ALFORD.—Jan. 21, at Southsea, Samuel Alford, M.R.C.S., young est son of Henry Alford, F.R.C.S., of Taunton, aged 58.

COLLIER.—Jan. 24, at Brackley, Northamptonshire, John Collier, M.R.C.S., in his 80th year.

CRONIN.—Feb. 1, at Claremont House, Brixton, Edward Cronin, M.D.

DAVISON.—Jan. 28, at the residence of his friend, Major K. Cumming, The Firs, Hounslow, H. A. Davison, M.B., second son of Henry Davison, Esq., of Armagh, Ireland, aged 26.

GRIFFIN.—Jan. 29, at the Crescent, Monkstown, Richard Griffin, M.D., L.R.C.S.E., L.K.Q.C.P.I.

NUNN.—Jan. 23, at The Oaks, Colchester, Roger S. Nunn, M.R.C.S., aged 69.

HEADACHES IN CHILDREN. (a)

By W. H. DAY, M.D.,

Physician to the Samaritan Hospital for Women and Children.

WHEN I was honoured some time ago by a request from the Harveian Society to read a paper this session, I hesitated, fearing that I might fail to introduce any subject in practical medicine which had not been worn threadbare by repeated discussion. Aware, however, that the members of this Society are essentially practical, that they live, as it were, with disease as it actually exists, and have great opportunities of watching its course and progress, I felt that I had no right to refuse the request, and that if I failed to impart information myself, the introduction of this subject for discussion would elicit something new and profitable; some facts, at least, which would add to our stock of knowledge. The subject of headaches is so familiar, and its victims are so numerous among all classes of the community, that every practitioner is acquainted with the malady as it presents itself in the course of his experience. If I say a few words on the two great factors of headache from a pathological point of view, I hope to make the subject clear to some extent. In the cerebral circulation there is a close relationship existing between the nerves and blood-vessels. There may be too little blood in the brain, in which case we speak of *cerebral anemia*. There may be too much blood, which we term *cerebral hyperæmia*. Then, too, the amount of blood in the brain is much influenced by the fulness of the ventricles, the subarachnoid spaces, and the lymphatic spaces, or sheaths surrounding the cerebral blood-vessels. The watery fluid which these spaces contain is identical with the cerebro-spinal fluid, and they communicate with one another. When the brain is anæmic the spaces are large; when hyperæmic they are small. Whatever significance we may attach to the headaches of adults, and however

we may be disposed to neglect their treatment, there is no doubt about the importance of attending to the headaches of children. Neglect in the early treatment of a headache in a child often invites ill-health, and terminates in irrecoverable disease.

When a child complains of headache our most careful scrutiny is demanded, and if it be too young to describe its sufferings, its manner and appearance are highly suggestive of some cerebral disturbance. Look at the little child of some ten or twelve months old, who is well developed, and comes of healthy parents. There is the excitement of dentition, and the little thing is observed to put its tiny hand to its head, which it rolls, perhaps, from side to side, and the anxious mother at last detects a slight irregularity in the muscular movements of the eye-ball. Reflex nervous irritation is conveyed through the fifth nerve to the brain, and irritation so awakened may be followed at any moment by a convulsion. The child is wakeful, uneasy, and restless. The brain, so needful of rest at this early period of life, is susceptible of mischief. I think there is hardly a practitioner among us who, on looking back, has not, in the course of his early experience, had reason to think he has overlooked these significant symptoms, and at the same time felt surprised at having neglected them. Habitual headaches in older children indicate an exhausted and irritable brain, and if intellectual exertion be carried too far in such cases mischief is likely to ensue. It seems extraordinary that educated men who have the care of young persons should not see this danger in the anæmia produced by over-study, the irritability and excitability of manner, and the impossibility of concentration, so necessary to the accomplishment of any undertaking. If intellectual exertion be carried beyond a certain point, the brain becomes anæmic, fatigued, and the nutrition in the ganglionic cells of the cortex becomes impaired, diseased, or in some way altered from health. Whatever may be the exact change in these cells, due, perhaps, in a great measure, to the absence of healthy blood, the inference is most probably correct, that children so suffering cannot readily grasp new ideas; and if strong and powerful efforts are put forward in this direction, the knowledge is not retained, the object is

(a) Read before the Harveian Society, February 2, 1882.

frustrated, one idea is mixed up with another, and confusion results. This, I apprehend, is just enough to illustrate the grand problem that the body must be looked to as well as the mind; and the younger the child, the greater is the necessity for the delay of intellectual training. And it does strike one as very extraordinary that the nervous system, which is the last to attain complete development, should be the first to be overtaxed in this age of forcing and strain, when revolutionary ideas are apt to overrule the judgment. It is not that the moderate exercise of the brain in early life is injurious; on the contrary, it is conducive to health. The mind is then flexible and plastic, impressions are enduring, and habits of concentration are easily acquired. It is the premature and excessive exercise of it which is prejudicial when the bodily powers need the chief attention.

No rigid rules—no cast-iron system will do for the training of all children. All are not cast in the same mould. Any system of education must be elastic, since mediocrity is the rule, and if more be expected of some children whose physical development is at the same time feeble, then disease or premature ill-health is the consequence.

Headaches are often *hereditary*; they have attacked children of the same family who have been brought up at a distance from one another, and whose surroundings have been quite different. In such cases there is something peculiar in the nervous system itself—a tendency to nervous disease. It will, I think, be often found on inquiry that the parents of such children are liable to nervous disease, nervous exhaustion, paralysis, &c., and perhaps some children of the family have had epilepsy, chorea, or asthma.

In many instances, too, there is some faulty condition of the blood. The brain badly nourished, through a scanty supply of blood, and that poor in quality, loses its balance, and cannot resume its tone.

I will now briefly allude to some of the varieties of headache in children. *Neuralgic* headache (one-sided headache) is not a very common type in children, but it oftener occurs than is generally supposed. So far as my experience goes, it has been met with chiefly among three classes of children: 1. Those of the neurosal temperament, whose nervous system is easily fretted, excited, and therefore sooner exhausted. If such children are pressed too much with their studies, then they the more readily suffer. Any degree of intellectual exertion is exciting to children of timid and delicate constitution, who are not only too anxious to learn, but cannot throw their studies off the mind. 2. Those children who have been reduced by some long and exhausting illness, in-door confinement and bad air. 3. Those born of delicate parents, and who are badly fed.

A striking example of the latter comes vividly before me. A girl, 12 years of age, thin and pallid, was said to have had an attack of erysipelas three years before she came under my notice, when I saw her for severe neuralgia. The pain began in the right temple, and remained at this spot more or less for fourteen days; then it passed over to the other side of the head, where it stopped for three days, and then returned to the first-named spot, where it remained at the time I saw her. It never attacked the top of the head, nor the occiput; nor did it ever cause sickness. The child looked half-starved; never got meat or milk, and lived chiefly on bread and tea. Her home was dark and miserable. For the first ten days of treatment she was relieved by citrate of iron and bromide of potassium. Then the pain returned in the right temple, for which an effectual remedy was found in arsenic and quinine.

In March, 1881, I was asked to see a little girl, 11 years of age, who, like all her brothers and sisters (of whom there were seven), was pale and delicate. A common cold, attended with enlarged cervical glands and sub-acute tonsillitis, was followed by severe paroxysms of neuralgia on the right side of the head, fullness of the

conjunctival vessels, and lachrymation. The pulse was very weak, and did not exceed fifty beats a minute when the pain was present. The patient had been subject to this form of headache from the age of four years. She had never lived in an aguish district, nor had she ever been the subject of more than the ordinary diseases of childhood.

A nervous and fidgetty boy, 10 years of age, with a cardiac murmur of anæmic origin, was seized with severe neuralgia of the right eye and temporal region in November, 1881. It was accompanied with sickness and lachrymation. Learning, which was a great effort to him, was persevered with against my advice. A month later he had chorea, when the headache ceased; but the choreic movements have continued up to the present time; and any effort at study would not only increase them, but renew the headache. I could multiply such examples as these.

Neuralgic headache in connection with dental caries is by no means uncommon in children from six to twelve years of age. Whenever the headache is one-sided, the mouth should always be examined, for a decayed tooth may be keeping up the pain, and if so, cod-liver oil, iron, quinine, and arsenic will be of no service. In January, 1882, a little boy six years of age was brought to me with severe neuralgia of the right side of the face and head; his mother said he would cry by the hour together, and was afraid to eat. On examining his mouth the second molar tooth was much decayed, and from this the pain evidently sprang. A dentist was consulted, and I have no doubt that he removed the offender. During the second dentition, when the teeth are forcing their way through tightened gums, neuralgic headache is occasionally met with. I have known the pain at once relieved when the gum lancet has been freely used. Mr. Nunn has related a case of supra-orbital neuralgia in a young lady of 11, which yielded to the lancing of the second molar tooth. (a) When during the second dentition the teeth are slow in appearing, neuralgic headache involving the fifth nerve, as they ramify over the brow and temple, is frequently very acute in boys and girls.

Another class of headache is that which is *nervous* and *congestive*. The term "*nervo-hyperæmic*" was given to it by the late Dr. Symonds, of Clifton. It is a condition in which the cerebral vessels are overloaded, and the nervous element is disturbed also. This form of headache is met with in children of both sexes, and is as much due to cerebral hyperæmia as to nerve disturbance. Shocks to the nervous system and overloading of the digestive organs are among the most frequent causes. The pain is, for the most part, confined to the forehead, and seldom seizes any other part of the head.

A healthy-looking and well-nourished boy came under my notice when nine years of age. He had suffered from diphtheria and whooping-cough. In his fourth year he was seized with frontal headache, after an accident by which his nervous system was severely shaken, but which did not involve his head. The attacks lasted about a week, and were considered bilious; he was sick, lost his appetite, the eyelids became dark, and he could not bear any noise, especially that of children playing about him. When the attack commenced there was much congestive excitement, the pulse was full and frequent, the skin flushed, and the temporal arteries throbbled.

Previous to the pain coming on, he passed a quantity of pale urine, his extremities were cold, and his face was pallid. In the morning he would be feverish, and complain of a burning sensation all over him, and great general discomfort. He had two attacks in a year, one of which lasted a month. Salines, mercurials, and arsenic had been ordered by his medical attendant, but his general condition was good when I saw him, and the attacks, although lasting for some time, were very rare. I recom-

(a) *British Medical Journal*, May 5th, 1877.

mended the simplest diet, a mild aperient occasionally, and ten grains of bromide of potassium twice a day. A year afterwards I heard that he had no return. These headaches often begin as early as the sixth year, when the mind is being exerted, especially if such children are delicate, and of nervous temperament. As time passes on, if nothing is done to relieve them, the attempt to read or to fix the attention on anything, a strong light or noise, will induce a seizure. The truly sick and bilious character of the malady becomes changed with more impaired health; pain now chiefly affects the top of the head, the headache of anæmia, or one side of it. In the latter situation it is a genuine neuralgia. But it is often noticeable that the same patient will get row and then a genuine bilious attack, in which the tongue is furred, the urine is turbid, and the vomiting is so urgent that the bringing up of bile, and loss of all appetite, are very unlike the former variety.

These two kinds of headache are as much opposed to each other as pleasure and pain, or heat and cold. Whatever circumstances are present in relation to the one are absent in the other. The nervous system is not in the same state; its vitality is heightened in the one case, it is lowered or exhausted in the other. If we look at the rapidity with which the one is sometimes followed by the other, as it is in persons of a mobile or sensitive temperament, it is probable that the vital functions are easily depressed. Pain is to be estimated by comparison, and it cannot be present to any great extent without influencing the vital functions. Most agonising cases of congestive headache are occasionally met with in children the subjects of confirmed epilepsy, and those suffering from advanced mitral disease of the heart with hypertrophy.

Headaches are common in ricketty children, due to brain exhaustion, and to pressure from an increase of serum both in the lateral ventricles and between the convolutions. The head gets large, whilst the face appears to shrink. The children so suffering sleep badly, toss about at night, and are excitable and peevish during the day. Confinement to school and study, deficient or bad food, will often bring on a seizure by lowering the general health. Bromide and iodide of potassium, belladonna, &c., are useful in these cases. In the intervals of the attack cod-liver oil and pure air are not to be forgotten.

(To be continued.)

VACCINO-TUBERCULOSIS AND VACCINO-SYPHILIS.

By J. CAPPIE SHAND, M.B., C.M.,

Physician for Diseases of Women and Children, Glasgow Public Dispensary.

A PAPER was read on the 3rd of this month by Dr. Wolfe at the Glasgow Medico-Chirurgical Society, in which he described a case of tuberculosis affecting the eye. He pointed out that a small particle of the tuberculous mass having detached itself, gravitated through the clear fluid, and itself became the centre of tubercular development.

I would call attention to the fact that this case is of great importance in visually establishing the truth of the danger of transmitting that disease through the medium of vaccination from one individual to another. Moreover, as it is quite a recognised fact that local tubercle is developed by local inflammation, especially in the subject predisposed to tuberculosis, and bearing in mind that vaccination is a local inflammatory process, it becomes clear that a probability almost amounting to a certainty exists, that tubercle may be introduced to the previously healthy individual through vaccination. Hence, it is necessary, before we take lymph from one infant to inoculate another, to examine, not only the condition of that infant, but also to inquire into its family history, which is practically impossible. Everyone knows that an

apparently healthy child may be tubercular, but this also applies to other diseases, notably to syphilis, and it may shortly substantiate my statement by recording the following case:—

Three years ago I was in attendance on the widow of a clergyman for a severely ulcerated leg. It did not look syphilitic, but as it would not yield to ordinary remedies, I afterwards used successfully the green iodide of mercury. I then obtained the further information that a child of hers contracted syphilis "through a wet nurse," and after the discharge of the latter the lady had a chancre on her mouth, the result of which I have just mentioned. This boy, however, although having an occasional rash looked so healthy that one of our first medical men, who was then attending, expressed his urgent desire to obtain lymph from the child after being vaccinated, which I may add he secured.

All I have to say in favour of animal, rather than humanised lymph is, that a breeder of cattle selects for breeding purposes those cattle which he considers healthy and free from disease, and consequently, I would expect greater immunity from hereditary disease amongst them.

I think syphilis may frequently be produced as well as tubercle, and remain in the system for a length of time before being recognised; and I am further of opinion with reference to vaccination that it should be optional, although apparently desirable, and that it should be put upon such a footing as to prevent it from propagating such diseases as tuberculosis and syphilis.

A VISIT TO THE HOWLING DERVISHES AT CONSTANTINOPLE.

By H. N. D.

THERE is perhaps no large city where it is more difficult to obtain information upon subjects which are at all outside the scope of every-day life than in the Constantinople of 1881. The European residents know and care about little beyond the course of exchange; the hotel people are apathetic and ignorant, and the professional *dragoman*—his stereotyped description of mosques and tombs once exhausted—seems to be absolutely unobservant. He is at least barren of all information which a visitor who cares to know more than *Murray* will tell him, would like to acquire. You see some unknown drug in the bazaar, and want to find out its name and use; he cannot even translate its Turkish synonym into any European tongue. You want to buy some hashish, he has never even heard of it—to understand the import of some constantly recurring street scene, he never appears even to have noticed it before. It is, therefore, not surprising that on such a subject as a religious observance the most complete ignorance should prevail on the part of those with whom the ordinary tourist can expect to come in contact. It was this difficulty which presented itself to me when a few weeks since I proposed to myself a visit to the *Tekie* or *Convent of the Howling Dervishes* in the city of the Sultan. There are two of these places on the Bosphorus, one at *Scutari* and the other in a deep ravine which lies between *Pera* and the river. It was this latter which I visited. It is about half an hour's walk from *Misseri's Hotel*, and although a carriage can be had, a great part of the road is so steep that in any case much of the journey must be made on foot.

It is noteworthy that while every book of Eastern travel contains an account of the evolutions of the dancing (or as they should more properly be termed the *turning*) dervishes, the proceedings of the sect known as "*les hurleurs*," or howlers, are either not mentioned at all or are dismissed in a

few words. It is not of course clear to the European mind why one set of devotees should turn and another set shout, but no one who has seen either or both modes of exercise can avoid the conclusion that they are the outcome of that form of religious enthusiasm which makes the performance of any peculiarly difficult task an acceptable offering to the Deity. There are some general features which are common to all the orders of dervishes, and if I shortly summarize these, the purport of the scene which I am about to describe may be somewhat better understood. The *tekie* or convent of the Turkish dervish is not a house of retirement, where in solitude he performs monastic vows, but rather a place of reunion where daily meetings for prayer take place, and where especially the weekly function of the order is performed. The dervish has in fact no permanently binding vow, but may at any time resume the life and avocations of an ordinary citizen. But each order has its own rules and liturgy, and above all its own peculiar observance based upon some mystical idea. It has its chief or *cheikh*, a personage of no mean importance, as may be gathered from the fact that the cheikh of the turning dervishes (in their case dignified by the title of *Mollah-houmkiar*, or religious sovereign) is the person who girds with the sword of Osman, a newly-elected Sultan. Under this chief are the *déds* or fathers, who correspond to the professed monks of our western institutions, and after these the *murids* or novices, affiliated to, but not by any means so strictly bound to the rules of the order. The *murid* may for example be a shopkeeper, a pacha, or even the Grand Vizier himself, if, for the sake of acquiring the religious influence so all important in the East, anyone of these should find it to his advantage to temporarily connect himself with the sect. Finally, all these orders have their good and their bad aspect; the good, that the shelter and food of the *tekie* are granted even to the poorest member of the confraternity; the bad, that whether they turn or howl or repeat in cadence, nine hundred and ninety nine times, the name of Allah—the *raison d'être* of one and all is, that by the performance of miracles, the exorcism of evil spirits, and the sale of amulets, they find, through the superstitions of the people, an easy way to its purse.

I knew little or nothing of all this when I found myself in the convent of the Howling Dervishes at Pera, so that my observations were unbiassed by any preconceived notions of what I saw. The *tekie* was placed in the midst of some gardens of fig and quince trees, and was entered by a courtyard which had a fountain in its centre. As I went in, under a shed on my right there was a man in a turban, so evidently at the receipt of baksheesh that I responded to his unspoken demand by a donation of some *paras*. Then I ascended a narrow stair, and someone showed me to a seat on a bench in a gallery which was evidently reserved for *giaour* spectators, for already seated there were several people from the hotel. The *function* had just commenced. My gallery was placed at one end of an oblong wooden room of which the prevailing colour seemed to me to be green, and round three sides of the floor of which ran a railing. The floor itself was covered with matting. Standing in a line against the wall opposite were thirteen persons. Some of these wore the orthodox turban and dress of the true believer; others, that modified modern costume which consists of a jacket, short drawers, and a *fez*. One was—the *fez* excepted—completely in European clothing. One was a negro and one a soldier. This variety of dress quite scattered to the winds any childish notions, derived from the Arabian Nights, that a dervish was an old, much-turbaned man with

a white beard, clothed in a girdled caftan, and leaning upon a staff. And indeed these scoundrels (I do not think I am villifying the minority in using the only word which fairly describes the impression created by the faces of the majority) were of all ages between eighteen and fifty, but there was not among them one old man. In front the cheikh squatted on a sheep-skin, (a) and beside him were two or three aides. The chief had not the villainous look of the rest of the brotherhood, but was a benevolent looking man, still in the prime of life, and wore the flowing green robe and the green turban indicative of the accomplished pilgrimage to Mecca. Several apparently quite unconcerned spectators occupied the space inside the railing, and a child in a turban and flowered yellow bedgown waddled about the unoccupied space on the matted floor.

As I took my seat, the thirteen had, as I have said, ranged themselves against the wall. Each had passed one arm over the shoulder of his neighbour, and the hand of that arm rested there. The other hand was, as well as I remember quite free. They leaned against the wall and against each other; next they swayed their heads, first to the left and then to the right, and then all bowed forward as if moved by a single impulse. Then at once they began a chant, which I took down quite phonetically, and not without some difficulty, under cover of my hat, being warned by a friendly elbow that note-taking might give offence. I know that books of travel tell us that a penitential Mohammedan says when at his prayers, "*La ila' ha illah la'*," but what these dervishes said, was—

"Eh, lo ah la, le ah uh
Ie, hoo, a hu, é, é, é,
Es a ba, a lalla, sta
Bra, ma chemia, à, à."

The movement and chant went on continuously for quite half an hour, gradually getting faster and louder. All the native spectators in the room became more or less infected, and kept time to the wail by bowing their heads. The cheikh had risen from his sheepskin, and beat time with his arm much like the conductor of an orchestra. That he also urged on his disciples was evident from his gestures. After some forty-five minutes of this, the performers were manifestly getting exhausted, but I certainly could not find it in my heart to pity them in the least. They were one and all panting with the exertion, and what had at first sounded like a dirge or coronech now became something between a bark and a howl: that is, the sound was sometimes sharp and quick, and sometimes prolonged. Very frequently it degenerated into a groaning "sough," which indicated the extent to which the physical powers of the performers were being taxed. It now became quite clear that they could not hold out much longer, and they did, in fact stop, but it was only to form a circle, apparently for prayers, and after an interval of at most three minutes, to commence *de novo*. I was unable to follow this, so to speak, Second Act, because my attention was now drawn off to a new development. But the excitement of the performers had now reached such a pitch that their cries and contortions could only have been equalled had an exceptionally fanatic corps of the "Salvation Army," locked up in a lunatic asylum, surreptitiously got at the whisky. There was a curtained entrance at the right side of the room, opposite to where I sat, and through this, sometimes singly, sometimes two and three together, came in a number of persons, some

(a) Not on a prayer-carpet, be it observed. The sheepskin is an evident survival of the pastoral origin of this, and some other sects.

apparently deaf, or lame, or blind, and others of whom it was not possible to say if there were or not anything the matter with them. One by one each advanced humbly, but in the most business-like manner possible, to where the chiekh stood, and saluted him. Then for the most part they lay down at full length while he coolly walked over their prostrate bodies. When the patient arose, the chiekh whispered something to him, and then either passed his hands over his eyes, breathed into his ears, or stroked down some part (most frequently the back or thighs) which was presumably affected. No women presented themselves, but several little children were brought in, and in their cases the *chiekh*, now supported by his assistant so as to avoid too heavy a pressure, walked over them just as he had the others, always beginning at the feet and proceeding upwards. I do not remember that I heard a single cry from one of the little victims, but I might have easily missed that in the Babel of sound. All the adult invalids having been operated upon and having been assisted to rise, first kissed the hand of the chiekh, then pressed it to the forehead, and having again kissed it, retired with a profound salaam. When all this was over, a number of articles which seemed to me to consist principally of crockery chimney ornaments and handkerchiefs, were brought in and presented to the chiekh. I, seeing him touch and inspect them with apparent approval, naturally supposed them to be presents from the benefited faithful, but, asking afterwards, was told that they had been sent to be "blessed." If this were so, I can only say that the blessing was done *en bloc*, and with praiseworthy promptitude.

Just at this stage, one of the youngest of the dervishes fell upon the floor, with frothing mouth and convulsed limbs, in fact, in an unmistakable epileptic fit. This seizure did not cause the very slightest surprise to anyone, and two or three of those present gently restrained and soothed the sufferer, who was soon, to all appearance, as well as ever. There was now nothing more to see, and I left.

There is one point in connection with this subject on which I wish to write without advancing any opinion, but rather with the view of eliciting information. This is the possible *sexual* motive of these exhibitions. It is quite true that no women took part in them, but it is also true that women are frequently, if not always, present as concealed spectators. I need only note, in passing, the admitted connection of some form of sexual excitement with all violently demonstrative religious displays; but it must not be forgotten that in the East the causes of such phenomena cannot be looked for from a purely Western standpoint, but are affected by customs happily but little prevalent in Europe. Sitting near to me in the gallery was a medical man who was strongly impressed with the idea that the whole performance must be looked upon in this light, and called my attention to the circumstance that towards its close two of the men had had seminal emissions. The character of their clothing was such as to make an evidence of this kind apparent. I saw the indications which were pointed out, and in view of the epileptic attack could easily refer them to this, but taking into consideration the temperature of the room and the violence of the exercise, I do not feel certain that they might not be due to other causes.

It is expected that the Home Office will appoint Professor E. Ray Lankester, F.R.S., to the Chair of Natural History in the University of Edinburgh, recently vacated by the resignation of Sir Wyville Thomson.

Clinical Records.

MIDDLESEX HOSPITAL.

Case of Strangulated Inguinal Hernia—Operation—Death.

Under the care of Mr. HENRY MORRIS.

[For the notes of this case we are indebted to Mr. W. ROGER WILLIAMS, F.R.C.S., the Surgical Registrar.]

THE patient, a clerk, *æt* 24, was admitted into the hospital on Jan. 6th, at 7.10 p.m., with the following history:—

Six days ago he strained himself in lifting a heavy piece of timber; at the time he was not conscious of having sustained an injury. On the morning of the fourth day after this occurrence he vomited several times, and then noticed a swelling in his left groin. He has since kept in bed; vomited frequently; the bowels have not been moved, and he has lived chiefly on slops.

Condition on Admission.—The patient is a thin, pale man, looking haggard and distressed, with dark areolæ round the eyes.

On admission, he was in a state of collapse, the skin moist and clammy, the extremities cold. Pulse, 110, small and weak; temperature, 98° F. He continually vomits a grumous, dark-brown, acid fluid, which at first had not a faecal odour, though this soon became apparent. There is a tense tumour in the scrotum on the left side, about the size of a fetal head, tender on even slight manipulation; this was readily determined to be an inguinal hernia.

The abdomen was resonant on percussion, not much distended, and tender only in the vicinity of the left inguinal region.

At 9.45 p.m. the symptoms were aggravated and the vomit distinctly stercoraceous. Mr. Morris performed herniotomy. Taxis had been tried outside the hospital, so it was not resorted to. Anæsthesia being induced, a nearly vertical incision, about 3 inches long, was made in the left inguinal region over the neck of the tumour. When the sac was opened a considerable quantity of blood-stained fluid escaped, having an offensive odour. It contained a large piece of omentum, not much damaged, as well as three or four coils of small intestine of a dark port wine colour, but retaining their lustre, evidently severely strangulated, and in a condition bordering on gangrene. The stricture, which was at the neck of the sac, was divided upwards. The omentum was transfixed by three double ligatures and tied as three pieces; the part beyond the ligatures was then excised. The bowel was gently returned into the abdomen, great care being taken not to push it beyond the internal abdominal ring. The wound was closed by sutures, and a simple dressing applied.

There was recurrence of the sickness after the operation, but the vomit had not a faecal odour. The other symptoms were unrelieved.

The patient died at 8.30 on the following morning.

This account of the case is mainly from the notes of Mr. Waldron, the Senior House Surgeon.

Autopsy seven hours after death: weather mild: post-mortem rigidity well marked. An empty hernial sac extended down the left inguinal canal, nearly to the bottom of the scrotum. The testicle was outside the back of the sac, near its lower part. The inguinal canal was patent, the little finger could be passed along it into the peritoneal cavity. The abdomen was distended. The visceral and parietal layers of the peritoneum, at the lower part of the abdomen, were injected; and the adjacent coils of intestine were slightly glued together. A considerable portion of the great omentum had been removed. Nine inches of the ileum, at about its middle part, had been strangulated in the hernial sac. There was no rupture of the gut. Where the bowel had been nipped by the neck of the sac it had a greenish yellow appearance, as of incipient gangrene. The intervening portion was very deeply congested, but the peritoneum had not lost its lustre. The mesentery corresponding to this part of the gut, which had descended into the hernial sac, was much congested, and in two places there were spots of hæmorrhage beneath the peritoneum; this part of the bowel contained blood-stained fluid. Both sides of the heart contained partially coagulated blood. The lungs were congested, especially the bases posteriorly.

Liver smooth, pale—weighed 42 oz. Right kidney congested; left ditto, pale. Spleen, large—weighed 6 oz. No other changes worth noting.

The autopsy was performed by Dr. Fowler, and this account is from his notes.

Special.

FRANCE.

[FROM OUR SPECIAL CORRESPONDENT.]

EXTIRPATION OF A FIBROUS TUMOUR.—At the meeting of the Académie de Médecine, M. Depaul communicated an interesting case of an enormous fibrous tumour impeding the progress of labour, and which he extirpated successfully. The subject was a woman *æt.* 32, who, a few days before her entry into his service (Hôpital des Cliniques), felt something issuing from between the labii, and a midwife being called, announced that the tumour consisted of a portion of the placenta that had become detached. A medical man being subsequently called, confirmed the opinion of the midwife, and ordered the woman to the hospital, where she was seen by M. Depaul. On examination M. Depaul found a tumour about the size of the closed hand outside the vulva, of firm consistence, and exhaling a very fetid odour. On introducing the finger the vagina was found to be completely filled with the tumour, so that it was impossible to penetrate as far as the os. Further examination was postponed to the following day, but that same evening labour set in. The tumour had considerably increased in volume, and was in such apposition to the vulva that it was impossible to pass the finger into the vagina. The waters had burst, and the child, to judge by the intermittence of the heart beats, was evidently suffering. There was no time to be lost, so M. Depaul drew down the tumour by degrees with the hand. By an attentive examination of this enormous mass he was able to discover its point of implantation, which was situated on the left part of the anterior lip of the os. By the bistoury the ablation was effected, and there was no hæmorrhage. The child in a few minutes followed; it was alive, and has since, as well as the mother, done well. An histological examination of the tumour, which weighed nearly 4lbs., proved the mass to be composed of connective and non-striated muscular tissue, with some irregular cavities containing a sanguineous fluid. A provincial member related another interesting case of a voluminous tumour (*choudrome*) occupying the right side of the thoracic wall and penetrating into the mediastinum, even to the pericardium. The tumour, which was of 14 years' growth, was a little larger than the head of a new-born infant, and situated upon the fifth right intercostal space, and extending to the corresponding border of the sternum. The consistence was that of cartilage, and in some places that of bone. The skin, which was of natural colour, moved freely over the tumour. An operation having been decided upon, a crucial incision was made, and the cutaneous flaps dissected. The greatest part of the base of the tumour was easily detached, but over the intercostal space it was found necessary to cut into the mass itself, as the chondrome appeared to pass through the space in question, going from without inwards. The knife was still carried to a depth of an inch, but the morbid tissue penetrated still further. The wound was closed, except over the excavation. During the three weeks which followed the operation, *débris* of the morbid tissue were extracted. The finger introduced into the wound touched the heart. At the end of two months the wound was entirely healed, and although

a considerable period has elapsed since then, the tumour has not returned.

USE OF IODOFORM.—Iodoform, it would appear, cannot be used indiscriminately, even in external applications, without producing toxic effects. A German medical journal gives the details of two cases of poisoning solely due to iodoform dressing. No other cause of death could be discovered, and the symptoms in both cases were identical. The cerebral symptoms were the most pronounced, consisting in a stupor from which the patient was aroused with difficulty, and to which soon succeeded coma. There was also paralysis of the sphincters and aphonia, contraction of the muscles of the neck, retraction of the abdominal muscles, and a very frequent pulse. The temperature was normal. In the first of these cases over five ounces of iodoform were used for caries of the bone. The toxic effects appeared on the second day, and death ensued four days afterwards. In the second case over four ounces of iodoform were employed, and for nine days the patient did well, but on the tenth, symptoms of poisoning set in, and death occurred six days afterwards.

FRACTURE OF THE PATELLA.—M. Poinot, who has particularly studied fractures of the patella in relation to its treatment, gives the following *résumés* of his researches:—"Articular puncture ought to be practised each time that there is considerable effusion. After the tapping, and in cases where the ordinary apparatus is insufficient, recourse might be had to osseous suture as recommended by Kocher. In every case the apparatus should be closely watched until the swelling subsides. Opening of the articulation for osseous suture is to be recommended in recent fractures where the effusion has not been sufficiently evacuated."

A NOVEL REMEDY.—Your correspondent was called lately to see a boy of ten who was reported to be suffering from attacks of epilepsy. On arriving at the house he found the child sitting up in bed apparently in perfect health. The mother attributed the happy condition of her son to the treatment she had adopted, which for the benefit of your readers I give in full. A live cat was caught and killed, the head taken off, and the belly opened down the whole length; the intestines were extracted, and then both halves were, all smoking and hot, applied to the stomach and left *in situ* for twelve hours. However, the mother said the poor cat smelled so awfully (I should think it did) that it was with the greatest difficulty she persuaded her son to keep it on the prescribed time. This odour was, however, by no means attributed to the cat by the parent, but to the disease. I may add that the convulsions were excited by the presence of worms, that a dose of *Koussé* soon expelled.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society of Ireland was held on Friday evening, Jan 13th, 1882, in the Albert Hall, Royal College of Surgeons.

Mr. B. WILLS RICHARDSON, F.R.C.S., presided.

Mr. TUFNELL, hon. sec., read the minutes of the previous meeting, which were confirmed.

MORBID SPECIMENS.—(1). TUMOUR IN OBTURATOR HERNIA.
(2). A CASE OF PHARYNGEAL OBSTRUCTION.

Mr. HENRY GRAY CROLY exhibited a specimen of obturator hernia, being the first of the kind in his experience at the Society. The patient was a woman, *æt.* 70, admitted into the City of Dublin Hospital suffering from all the symptoms of intestinal obstruction. He had previously been asked to see the case by Dr. Puroell, under whose care the woman had come

six days before her admission, when she complained of a colicky pain in the abdomen. Up to the 17th the bowels were regular, but on the 19th symptoms of intestinal obstruction set in, with vomiting and great pain. There was no tension of the abdomen. He had made a careful examination for hernia externally, without discovering any tumour. On the 21st, symptoms of collapse set in suddenly, and the interesting point arose to get her out of the state of collapse and perform abdominal section to discover the cause of the obstruction. Though hypodermic injections of ether were used, the collapse continued till she died. On the post-mortem examination signs of peritonitis were discovered, and a small tumour. The tumour (which he exhibited) was found in the right thyroid foramen, and with the slightest pressure on the intestines it was easily reduced into the cavity of the abdomen. There was no dulness on percussion where obturator hernia was usually found, and there was no tension. The specimen was interesting in connection with the question of laparotomy. Where no tumour was found, the habit was to poultice, &c.; but had the woman been sent at an earlier stage into hospital, and abdominal section been performed, she would have had a fair chance of being relieved of the strangulation. Here the characteristic symptom of obturator hernia—namely, pain down the thigh from pressure on the nerve, was not present, the tumour being small, and not giving pressure sufficient to produce that symptom.

Mr. THOMSON exhibited rather a curiosity in regard to the process of deglutition. The patient was a pensioner, who having received his pension went into an eating-house last week to dine. During dinner the specimen of beef stuck in his pharynx, and could not be dislodged. The man fell on the floor insensible, and was carried to the Richmond Hospital. The resident pupil on duty tried to remove the piece by passing the fore-finger of each hand back into the pharynx, seizing hold of the beef and drawing it into the mouth, but the mass was so large that he could not then extract it through the oral orifice, and he had to finish that portion of the operation with forceps. Artificial respiration was continued for some time without result. The cause of death was the wedging of the mass of beef, weighing two ounces, in the pharynx.

ADJOURNED DEBATE.—THE THERAPEUTICAL AND POISONOUS EFFECTS OF CARBOLIC ACID.

The adjourned debate on Dr. Warren's paper, was resumed by

Mr. WHEELER, who said Dr. Warren in his paper had alluded to the local application of carbolic acid. He had himself read a paper before the Society last session, in which he showed clearly the disadvantageous effects of that drug, used according to what was termed Listerism—that was to say, the spray; and when of fixed strength, he had in that communication pointed out how one case of his was poisoned in a manner analogous to what Nussbaum had described as death by aseptic fever, and how another case of his was nearly poisoned. There only came within his immediate knowledge one instance of poisoning by the internal administration of the drug, in which case he did not arrive before death had occurred. It had been said that carbolic acid, being used in a slipshod way would account for many of the accidents. Well, it would be allowed that Mr. Keith did not use it in that way. He would accordingly read from the *Medical Gazette* his views in a leader entitled "Listerism—is it a failure?" "It has been said, and was repeated by Volkman and Kuget, that intra-peritoneal surgery was the touchstone of Listerism. Prof. Keith has been quoted by the world over again and again, as not only a warm disciple of Lister, but as illustrating in his remarkable success in ovariectomy, more than any other surgeon, the value of the antiseptic, or rather the Listerian method. No one can deny that so slowly were his few words uttered, that I can almost repeat them *verbatim*. You can imagine the effect much better than I can describe it, when he said that for several months past he had abandoned the antiseptic (Listerian) treatment altogether. True, he said, he had eighty successive recoveries under Lister's method, and stopping there it would be a wonderful showing; but out of the next twenty-five I lost seven. One died of acute septicæmia in spite of most thorough antiseptic precautions, three of unquestionable carbolic acid poisoning, one of renal hæmorrhage." He went on to say "that, out of the eighty consecutive cases, many came too near dying, that a large number got a high temperature—105°, 106°, 107° the evening following the operation, but they happened to pull through. He then

said that for four months past he had abandoned the antiseptic method (meaning Listerism) and relied upon perfect cleanliness, care in controlling hæmorrhage, and thorough drainage; that his cases were giving much less trouble, and he was getting more satisfactory results." If these words were contrasted with what he (Mr. Wheeler) had laid down in his paper—namely, surgical cleanliness, physiological rest and drainage, there would not be found much difference between what Keith had advocated and what he had named antiseptic surgery, in contradistinction to Listerism. The article continued that Prof. Keith said he had never much faith in Listerism, and would not have continued to use it so long, but for the fact that so many eminent men were carried away by it. But hear the reply of Lister, who was set down to close the discussion. To the dismay of his followers, he went on to argue the rapidity with which wounds of the peritoneum healed, and the remarkable absorbing power of that membrane, and therefore its ability to take care of its own exudates. He doubted very much whether in the hands of a skilful and careful surgeon it was not better to dispense with the antiseptic plan. He proceeded to say that he was not yet ready to give up the spray, but that if simple irrigation or lavation would prove as good he would say, "fort mit dem spray. I am not at all sure that before the next meeting two years hence I shall have abandoned the spray altogether." As to carbolic acid, he said, "I am forced to admit its unfortunate character." He kept again and again referring to abdominal surgery, but his manner showed that he was upset. The writer concluded by saying, "Well, if Lister abandons the spray and carbolic acid, and gives us no substitute, where is Listerism?" We had drainage, we had animal ligatures, we had air-proof dressings before. He (Mr. Wheeler) might add that Listerism was all but dead in London. It did not lessen surgical fever, as had been proved by Mr. Bantock, and the temperature previously mentioned in Mr. Keith's cases, besides his own experience. Dr. Smith had made such an excellent speech on using carbolic acid internally, that he had little to add. Were he called to a case of carbolic acid poisoning, he would use Glauber's salts as an efficacious remedy. There was utility in carbolic acid, as Mr. Franks had pointed out, for affections of the throat, but he thought it had failed in attaining what Lister claimed for it.

Mr. W. THORNLEY STOKER said so many aspersions had in the course of the discussion been cast upon carbolic acid as a poisonous agent, that he wished to state what he had himself observed, because the utterances of a Society like this carried a certain amount of weight, and it was well, therefore, the speakers on one side should not have it all their own way. He had seen the spray used in hundreds of cases, and never in any instance was the slightest symptom of carbolic acid poisoning produced, save one, a case of his own, where the carbolic oil was applied as a dressing to a large superficial burn. Professor Bennett had said so much on the last night of discussion in reference to applying the acid to cases of that sort, he had nothing to add, beyond expressing his belief that carbolic oil of the usual strength, 1 in 4, was a dangerous agent when applied to burns of a large extent. He had, accordingly, discarded the use of carbolic oil for burns; but except that one instance, he had never seen carbolic acid produce poisoning, nor had he ever heard of an authentic case of its doing so in the hospital practice of those around him.

Mr. HENRY GRAY CROLY remarked that he could not be present without testifying that he had no case to record of poisoning by carbolic acid. He had been one of the first to carry out antiseptic surgery according to Lister's method, which he did not adopt strictly until he learnt it from Lister himself, though he had long previously used the carbolic acid in the treatment of wounds. In every form he had used carbolic acid, applying it to burns with the greatest care. With regard to the spray itself, he contrasted his own practice now with what it was before he adopted Listerism. He had not such a liking for Lister as to be wedded to his method unless he believed it to be good. It was unfortunate to attach a man's name to an invention. However, he had not had anything like the same results in his own practice before he adopted Listerism as he had since, and therefore he thought he would be morally responsible for the death of any patient under his care where he did not adopt Listerism. He would not have an operation performed on himself except under the spray, and with anti-

septic dressings. He wondered what Keith meant when he advocated perfect cleanliness in 1882. Why, he (Mr. Croly) had learned cleanliness when he was a student. Dr. Geoghegan long ago adopted cleanliness, and prided himself on fresh air in the wards, and washing out wounds with chloride of zinc and Condy's fluid—nearly exploded now. If he were told he had used the opposite of perfect cleanliness in his early practice he would be ashamed of himself. Cleanliness and good surgery always went together, and the opposite of cleanliness (which meant dirt) and bad surgery also went together. For his part, he intended carrying out the antiseptic surgery of Lister until he found something better.

Mr. STOKES said there was one remark he heard with surprise, namely, that in the hospitals of London, Listerism was dead. Knowing, as he did, that in St. Thomas's Hospital, University College, King's College, St. Bartholomew's, and Guy's, the antiseptic practice of Lister was carried out with extraordinary care and accuracy, the remark was, at all events, uncalled for. Another remark he heard also with surprise was that the characteristic of the antiseptic dressings of Lister, or rather the result of adopting that practice, was a uniform rise of temperature—an increase of surgical fever he presumed was meant. That was entirely contrary to his experience. All his colleagues were present, and if he was wrong they were in a position to contradict him in stating that, if there was anything struck them more than another, it was the great diminution of surgical fever observable even after operations of the greatest magnitude. For the last five or six years there had been no operation of any importance—excepting always operations on the eye and about the mouth—done in the Richmond Hospital that had not been carried out in accordance with Lister's teaching and practice; and they had observed, not only no case of carbolic acid poisoning (as Mr. Stoker had already mentioned), but there was this remarkable thing, that in no case had erysipelas followed any operation in which the Listerian dressings were adopted. That was a very great contrast to what was experienced before the introduction of Lister's dressings, and when he looked back to what he was in the habit of witnessing as a student the contrast was still greater. Erysipelas was always a subject of dread and anxiety, and what was worse, hospital gangrene, which was unknown now, and was a disease that might be said to be stamped out. There had not been a single instance of erysipelas following an operation after the adoption of the dressings of Lister. He expressed regret that the practice which meets the approval of the greatest minds in surgery, not merely in England, but in France, Germany, and America, and which was universally sanctioned, should in this Society be laid open to such grave question, and even in the interests of the character of the Society, that the question should be raised at all.

Mr. HAMILTON pointed out that the discussion was diverging into the merits and demerits of antiseptic surgery.

The CHAIRMAN said Dr. Warren had in his paper alluded to the local effects of carbolic acid.

Mr. HAMILTON understood that it was as to poisonous effects. The discussion had drifted into the question of the merits and demerits of Listerism, which, having been so recently debated, he did not think it was necessary to raise again. Any man who had experience of the action of carbolic acid should not withhold it from the Society, and therefore he rose to give his own impression as to the effects it produced. He believed he was one of the first surgeons to adopt the plan suggested by Lister many years ago, when using putty and lead foil. He remembered Dr. Fleming bringing him to the Richmond Hospital to see Lister use the application, and since then he had used it himself, and witnessed the effects of carbolic acid applied locally. At Steeven's Hospital no capital operation—he might almost say no operation at all—was performed without carbolic acid, and so far as his experience went, he had never seen a bad result that could be set down in any degree to the poisonous effects of carbolic acid.

Dr. H. BENSON observed that Mr. Stokes had alluded to the non-usage of carbolic acid in ophthalmic surgery. In St. Mark's Hospital they had been using the spray for two years. They could not use the regular dressings. During the last session there were only two cases in which operation was followed by suppuration, and these were cases in which carbolic acid was not used—complicated cases, in which it was accidentally omitted.

Mr. THOMSON added his experience to that of Mr. Hamilton and the other speakers as to the effects of carbolic acid in the treatment of wounds. He was quite unacquainted with what carbolic acid poisoning was, having never seen a case of it, nor had he seen the discoloured urine, nor the great increase of temperature. There seemed to be a tendency among some persons, the moment carbolic acid was mentioned, to flare up, as if there was something specially poisonous in the name of it. He was sure there was no operating surgeon present who was wedded particularly to that special material in the treatment of wounds, each of them simply taking it so far as his own experience, and that of others, went, as the best dressing yet obtainable. There was no doubt, however, that carbolic acid was a poison, and that in certain cases, either from its absorption through the external parts, or from being administered internally, it had been followed by death. But he hoped it was not to be maintained that because those fatalities had occurred they were to throw it overboard altogether. If that line of argument were admissible, they should throw overboard one-half of the Pharmacopoeia. Opium and other potent and useful drugs had produced more deaths than could be ascribed to carbolic acid. If people used carbolic acid injudiciously there must be unfortunate results. They had been told by one speaker, that after some cases of ovariectomy he had had his hands numbed and made almost useless for fourteen days, and he charged himself, with what degree of justice he perhaps would best know, with having caused the death of three patients. If a surgeon used carbolic acid which produced such an effect upon his hands, it was not to be wondered at that when applied to the peritoneum of three women it should cause their death. In reference to Mr. Keith, no doubt he had made a recantation as to the use of carbolic acid; but alongside of it should be put his emphatic praise of the carbolic treatment as applied by Lister, to the effect that he would have no hesitation in passing from the post-mortem room after holding an examination and proceeding to operate on a woman's abdomen for the removal of an ovarian tumour, provided he were protected by the Listerian method. Nothing stronger than that could be said, and Keith had said nothing so strong in his recantation of the use of the plan thus praised. On the last occasion, Dr. Cole of San Francisco, took an opportunity that was not justified by the facts, of charging Lister with having bolstered up his case, and altered before publication what he had said. While he (Mr. Thomson) was not there as an apologist of Lister, but simply following the lines which the discussion had taken, it was certain that anyone who knew that surgeon, and the reputation he held in the profession, would not concur in a charge of that kind, which was simply one of fraudulent representation. Dr. Cole was extremely modest in expressing the experience he had had of surgery. He was not going to yield his experience of any kind of operation, he said, to anyone in the world. He was kind enough to say they were all following a craze, and all who believed in Lister were like so many women caught by a fashion. Further, he represented that they were simply a flock of sheep ignorantly following a bellwether, while he and those who thought with him posed as the wise sheep. He (Mr. Thomson) was not ashamed to be in the company in which he was; and in the adoption of carbolic acid by Lister, and as carried out not only by him, but by men who certainly were not fools, they had had successes unparalleled, as a general rule, by any other system of treatment.

Surgeon-Major MYERS, (Coldstream Guards), was glad to find the remark as to Listerism being dead in London corrected by Mr. Stokes. At the Medical Congress one great question in the military section was, not the effect of Listerism in the treatment of wounds, but how surgeons could manage to treat wounds in the field by Lister's method. There were present representatives from most nations, and certainly none of the military men referred to the doubt, but to the difficulty in attempting such treatment. He was glad to find the method so highly supported, as most of the eminent military surgeons were recruited from the Irish schools, and no doubt the remarks of the Society would be seen by the various medical students of Dublin.

Mr. O'GRADY, referring to the alleged diminution of erysipelas from the use of carbolic acid, said he had been sixteen years attached to Mercer's Hospital, and never saw the disease there, except it was imported, and that was of rare occurrence. He did not want to express his colleagues'

opinion; but they had, like himself, giving up using carbolic acid, and he supposed it was because they did not believe in it. Statements had been made as to its injurious nature. He, too, had seen mischief follow from it. In a case of ovariectomy which he had performed, two or three days after the operation, while he was injecting an aqueous solution of carbolic acid into the wound, the woman, who was joking with him about safety pins, became suddenly insensible, and died in ten minutes. There was nothing that he could attribute it to except the use of carbolic acid at the time. He did not remember distinctly the details, as he did not intend to speak, but Mr. Wheeler had compelled him to get up. (A laugh). While he did not go the length of saying that carbolic acid was as injurious as some people asserted, he did not hesitate to say that, used in the sense of Listerism, it was a farce, and he looked upon it merely as an adjunct in throwing an unworthy mystery over the practice of the surgeon's profession.

Dr. ATTHILL—How long after the operation did the patient die?

Mr. O'GRADY—Three or four days.

Dr. ATTHILL said in that case it was not to be supposed that where no symptoms whatever occurred in the interval, carbolic acid had accumulated in the system and proved fatal.

Mr. O'GRADY—I do not remember the precise time after the operation. I did not speak of its cumulative effects, but of its immediate action.

Dr. ATTHILL said there was not the slightest doubt that carbolic acid spray had produced serious, and perhaps, fatal effects, but there was such a thing as the proper use and the improper use of it. As had been stated, it was used so strong as to paralyse a gentleman's hand. If they used too strong a spray in a woman's abdomen, it would most likely produce poisoning. He had performed ovariectomy thirty or forty times, and in more than three-fourths of the cases he had used the spray. However, he now believed that the spray was not advantageous, useful, or advisable, in ovariectomy; but for a different reason. He had never had reason to suppose that poisoning by carbolic acid followed; there was nothing in the urine to prove it, as suggested. But the reason he had given up using it was on account of the extreme coldness it produced wherever it fell. He had, however, in his possession a letter written to him two years ago by Keith, stating in effect—"The operation as now performed under the spray gives us such absolute safety that you could spend an hour in cleaning out or dressing the abdomen." Of this Keith had since recanted, but when he wrote it he had performed a couple of hundred operations.

Mr. WHEELER thought it right to say, as Dr. Cole was not present, that that gentleman had distinctly stated he used the spray 1 in 20, or 1 in 40, exactly according to Lister.

Mr. CORLEY remarked, in reference to the paralyzing effect of carbolic acid on the hands, that there was the greatest possible difference in the varieties of carbolic acid used. He had had his own hands in a condition of numbness from using the ordinary carbolic acid, but that effect was not produced since he used the absolute phenol recommended by Lister, and therefore the use of the inferior article might explain the disagreeable, and in some cases fatal results, that happened. Indeed, Professor Lister had stated that the ordinary carbolic acid was impure.

Dr. DUFFY had a perfect recollection of Mr. O'Grady's case, having been present at the time of the woman's death. As well as he recollected, a weak solution was injected into the woman's abdomen, and after the injection she suddenly collapsed and died rapidly. He made the post-mortem examination, and there was not a single morbid lesion to account for death. The heart was perfectly healthy. Skilled pathologists present corroborated his examination. It was not, however, an unusual event to have death follow from the injection of fluids other than carbolic acid, even water causing chilling in the abdomen and fatal collapse.

Dr. WARREN replied. He said some of the speakers had gone into the merits and demerits of the antiseptic treatment of wounds; and therefore he ventured to remind them of the opening paragraph in his communication, in which he disclaimed any intention of raising the question of the antiseptic treatment, and would also draw their attention to his closing remarks, in which he paid a tribute to the genius of Mr. Lister. Dr. Mapother had not stated whether the case in which he injected the acid into a nevus in a child, proved fatal or not. He (Dr. Warren) thought the symptoms in his case were more those of embolism than of poisoning by the

acid. With regard to the observations of Mr. Franks, he had only to say, that he merely mentioned cases in which he had found it useful from his own personal observation. He had never yet had an opportunity of trying it in diphtheria; but, of course, the treatment of the disease was well known to every surgeon. He alluded to the anæsthetic properties of the acid, and explained its probable value in whooping-cough upon this property of the acid. He was just as firm a believer in the antiseptic method of treating wounds as Mr. Fitzgibbon, but he did not think that they ought to complacently fold their arms and rest satisfied that carbolic acid was the best antiseptic. They ought to be progressionists in the fullest sense of the word, ever striving towards the best method of carrying their principles into practice with as much safety to their patients as possible. Many of the speakers seemed to have forgotten that Mr. Lister himself had long been endeavouring to find out a safer substitute for carbolic acid. With respect to the remarks of Dr. Smith, he had only mentioned in the most casual way, that the discolouration of the urine might be due to indican; and this view was put forward by Sir W. MacCormac in his work on antiseptic surgery. The cause of the colouration appeared to be still invested in much doubt. Husemann at first believed that the hæmoglobin was the cause of the colour, but he afterwards abandoned this theory because of the urine fully clearing up, after acidifying, and then heating, and especially because the odour of the acid was given off during the former process. There could be no doubt, however, but that carbolic acid existed in the urine in cases of poisoning, as the reaction to characteristic tests indicated; yet there must be also some new products formed, because the carbolic acid urine when subjected to nitric acid and afterwards potassium hydrate, and then concentrated, gave a blood-red, followed by a pea-green and violet colour. Carbolic acid added to the urine outside of the body, would yield this play of colours. Microscopical examinations revealed carbonaceous particles, and it was difficult to determine whether the particles had anything to do with the characteristic test mentioned, or not, although it seemed that they were the probable cause of the colouration, and possibly the factor upon which reaction depended. With regard to the test for carbolic acid poisoning, by examination of the urine, he would remind Dr. Smith that he had most distinctly stated in his paper that the normal sulphates were converted into sulpho-carbolates. The distinction drawn by Dr. Smith, between the total absence of the phosphates from the urine, and their inability to react to the baric chloride test by reason of their being rendered latent, seemed a distinction without a difference, in fact, a mere wordy controversy. Dr. Cole certainly was a strenuous opposer of the Listerian method, but he had yet to learn the details of Listerism, for he admitted himself, that the spray which was used in his cases caused numbness of his hands for fourteen days subsequently to the operation. Was it any wonder then that the patients died? He could not agree with Professor Beunett that the application of the acid in burns was more dangerous than in any other case. He had now used it in burns for ten years, and had never yet seen the slightest bad result follow, when applied in a sufficiently diluted form. He quite agreed with Mr. O'Grady that the existence of idiosyncrasy in many cases of carbolic acid poisoning was beyond all doubt, and this opinion was strongly put forward by Professor von Langenbeck. In the *American Journal of the Medical Sciences* for October 1881, a summary of fifty-six cases of poisoning by carbolic acid was recorded by Edward T. Reichert, M.D. In many of these, death took place from the application of the acid to the surface of the body in skin diseases, or its injection into the cavities of the body, or into the tissues. But he was not aware of a single case on record in which the spray, *per se*, proved fatal or even deleterious. The question really arose: Was the spray indispensable, or even useful? Professor Lister, at the surgical section of the London Congress, 1881, had stated "that his own results were so good that he shrank from giving up any of the details of the treatment by which he obtained them, although he quite admitted that he too, might at some future time be able to say *forti mit dem spray*; at present he could not accept irrigation as a substitute for the spray.

The Society then adjourned.

CONVOCAION of Oxford University has granted a sum of £250 for providing the Linacre Professor of Physiology with additional microscopes, diagrams, drawings, &c., for the use of students in the Physiological Laboratory.

WEDNESDAY, FEBRUARY 15, 1882.

DEAN SWIFT'S DISEASE.

A PAPER on Dean Swift's Disease in *Brain* for the current quarter, from the pen of Dr. Bucknill, unquestionably throws new light on what has long been a literary and pathological mystery. The nature of the malady, which vexed the life of the great writer, and ultimately ended his days, under a cloud of mental tribulation, has always puzzled his biographers, and the discussion of the subject has sometimes led to recrimination amongst them, as when Sir Walter Scott retorted on Dr. Beddoes who had hinted that perhaps a specific element had entered into the Dean's complaint, that "until medical authors can clearly account for and radically cure the diseases of their contemporary patients, they may be readily excused from assigning dishonourable causes for the disorders of the illustrious dead." More recent biographers, and notably John Forster in the charming fragment of a life history which he has left us, have been content to state the scanty facts that have been left on record concerning the Dean's sufferings and fatal illness, abstaining from speculation as to their origin and nature. But, still curiosity has not been laid to rest, for during last autumn, a literary worker interested in the old topic, invoked Dr. Bucknill's aid to solve his difficulties and, with a happy result, for it can scarcely be doubted that Dr. Bucknill, viewing the question in the light of the most recent neurological discoveries, has finally settled the point and determined the true character of Dean Swift's disease. His conclusion is, that Jona-

than Swift was the victim of labyrinthine vertigo, or Menière's disease, and that he was ultimately struck down by a clot or softening in the third frontal convolution of the left hemisphere, causing aphasia, right hemiplegia and brain wasting.

As we have said the facts that have been handed down to us concerning the Dean's illness, and the symptoms by which its progress was marked are scanty, but although scanty they are sufficient for Dr. Bucknill's purpose and amount, it must be admitted when they are marshalled together to be a conclusive proof of his proposition. The manifestations of the illness most frequently adverted to by the Dean himself in his correspondence are two in number, viz., giddiness and deafness. It would appear that at one time he was under the impression that the giddiness attacked him first, but a careful collocation of dates makes it evident that the deafness preceded the giddiness, the former coming on when he was twenty years old, as the result of a cold which he caught in England, and the latter when he was twenty-four years of age, as the consequence as he believed, of his having eaten one hundred golden pippins, at one time, at Richmond. The belief that this gluttony in green fruit was the real starting point of the vertigo which so greatly distressed him was firmly rooted in the Dean's mind, for it led to a lifelong abstinence from apples of which he was passionately fond, but still there can now be little doubt that this belief, like so many popular and self-concocted notions on medical matters was erroneous, and that the deprivations which it suggested were unnecessary. The vertigo may, more reasonably, be traced to the ear trouble, which began as ear troubles often do in catarrh, and which persisted for a certain length of time and reached a certain intensity before other symptoms supervened. Although "deafness" is the constant complaint in connection with the ear trouble; we know that it did not consist simply in deafness, for in several places in his letters and "Journal to Stella" he refers to being pestered and incommoded by noises in his ears. These noises are nowhere minutely described, so that we cannot say whether they partook of the tinkling, buzzing, or shrieking character most common in Menière's disease, nor whether they underwent an alteration in intensity immediately previous to the occurrence of what he called his fits, but the important fact remains that there were noises in the ears, which came and went, and deafness which was subject to occasional aggravations, and that the ear trouble, as is almost invariably the case in Menière's disease, was worse in one ear than in the other, the ear most affected in Dean Swift's case being the left one, an observation of great significance, we think, in connection with his subsequent pathological experiences. Whether there was any discharge from the ears or other external sign of aural disorganisation cannot be clearly ascertained, but it seems probable that there was, as ointments were certainly introduced into the external meatus, and as there was sometimes sudden relief from very decided exacerbations of deafness. The deafness went on increasing up to a certain point, but, unfortunately, it never resulted in complete loss of hearing. We say unfortunately, because, had it done so, the vertigo would in all likelihood have disappeared contemporaneously with the loss of hearing, and thus the Dean's

mind would have been relieved from the actual distress of the attacks, and from the gloomy forebodings which they kept constantly present to his mind. So constantly has it been noticed in Menière's disease that there is mitigation of all the symptoms when total deafness is reached, that it was proposed, before a better mode of treatment was discovered, to take means to hasten the establishment of total deafness.

The vertigo in Dean Swift's case, from what we can gather respecting it, was scarcely less characteristic of Menière's disease than the aural symptoms. It came on when his ears had troubled him for some time, and at first under the form of distinct crises of short duration separated by intervals of absolute calm. But as the affection progressed the crises tended to draw closer, to become commingled, and to constitute, as it were, a permanent vertiginous state, in the midst of which more or less frequent paroxysms appeared and reproduced all the phenomena of the old crises. The giddiness, when first experienced, consisted of genuine motor hallucinations, or purely subjective movements. The Dean's feeling being that there was rotation of the body on its vertical axis; but, ultimately, it seems to have been expressed outwardly in disordered muscular movements, for he speaks of tottering when the fit was on him, and laments that, under such circumstances, he walked like a drunken man. One other feature of Menière's disease is to be noted in relation to the giddiness, and that is, that it was liable to be induced or greatly exaggerated, by any sudden movement or by shaking the head. "My head is pretty well," he writes in his journal, "only a sudden turn at any time makes me feel giddy for a moment, and sometimes it feels very stuffed." The fits came on when he was standing, walking, sitting, or recumbent in bed; but any sharp or violent movement seems to have occasionally determined their occurrence or intensified their character.

But the accessory symptoms of Menière's disease were not wanting in Dean Swift's case any more than its essential features. Nausea and vomiting frequently marked the end of the attacks; cephalalgia was often experienced, and there were grounds for believing that there were pallor of the countenance and coldness of the surface during the fits. It is scarcely necessary to say that consciousness was never even momentarily in abeyance during the fits, and that they were not followed by stupor or drowsiness. Sometimes, when they were numerous and severe, he deplored a sense of restlessness and debility which followed them, but even after the worst of them we learn, and while they were actually going on he was capable of arranging his thoughts and composing with dignity and perspicacity.

As regards the later phases of Dean Swift's malady, it is tolerably evident that he had a certain degree of right hemiplegia—a discovery for which credit must be given to the late Sir William Wilde, who detected in the plaster-cast of Swift's head taken after death, and accidentally brought to light a hundred years afterwards, some drawing of the mouth to the left side. It is tolerably evident, also, that he had some impairment of language, though not, perhaps, aphasia, in the ordinary acceptance of the term. But in order to account for

these symptoms, we do not, like Dr. Bucknill, think it necessary to suppose some unreported or unobserved apoplectic seizure with clot in the left hemisphere. Most probable it seems to us that there was propagation of disease by contiguity of tissue from the left ear in which it was always worse than in the right one to the left hemisphere and its membranes, and that a state of irritation was set up in the temporo-sphenoidal lobe, which gradually spread to other groups of gyri, and which ended in degeneration and wasting. This theory adequately explains the irritability, malignity, and moral perversion which the patient displayed; his lapses of memory, his melancholy, his maniacal outbursts, his word-troubles, his fatuity, his death in a state of coma after prolonged convulsions, and the morbid appearances in his brain as far as these are described.

But whatever view may be taken of the final issue of Dean Swift's illness, no doubt can be entertained that Dr. Bucknill has marvellously elucidated all its stages, and has helped us immensely in our comprehension of an illustrious man, who must always remain inscrutable in some aspects. Dr. Bucknill's essay is alike graceful and interesting, and, although subtle, is never obscure.

RESIDENT HOSPITAL APPOINTMENTS.

A QUESTION of increasing importance to students is that of the method adopted for selecting from among the numbers who apply for resident hospital appointments the candidates best fitted to discharge the duties connected with them. In recent years a much greater degree of attention has been given to this matter, because of the rapid growth in the numbers of young men entering the profession of medicine at the commencement of each winter session. Formerly, when comparatively few men passed out from their school in the twelve months, there was no difficulty experienced in apportioning the various resident appointments among deserving students, so that every diligent pupil was enabled to complete his hospital career by securing the advantages of the experience conferred by holding a house-surgeoncy, or house-physiciancy, or both, as the case might be. At the larger and more crowded hospitals there has, of course, been at all times more or less competition for these offices, and in exceptional years in the past it may very well have happened that many well-qualified candidates have failed to obtain the wished-for appointment. Now-a-days, however, not only the principal hospitals, but even the smaller ones also, are so crowded with students that only a minority of them can hope to serve in official capacities on completion of their curriculum. In view, therefore, of the great advantages that are thus of necessity confined to a few of those who seek to share them, it may be well to consider how far they are justly and equitably distributed. In most cases the term of office is six months, while in some hospitals it is not unusual to extend this term by an additional three, or even six months. In favour of such a course it is urged that by retaining the services of a specially skilful resident officer the institution is benefited further than it would be by replacing him with an untried and possibly less well-qualified candidate. Against this should be placed the injustice that such a course in-

flicts on the students who are waiting for a chance of doing resident duty, and who have been steadily working with that object in view. To not a few young men who select the profession of medicine as a means of living, the sacrifice of half a year or a year in waiting for appointments is a very serious matter; it means not only the expenditure of so much extra capital as personal maintenance for that length of time involves, but also it defers the period of actual bread-making, a matter of unfortunately too common necessity among the younger followers of medicine. Hence it is desirable, and, indeed, it is a duty owed by the governing committees of hospitals, to provide those students who are anxious to hold resident offices with the earliest opportunities of obtaining the fulfilment of their wishes. This naturally suggests consideration of the plan on which the elections are usually conducted; and here at once we may admit that we see many objections to that ordinarily followed. As it is at present, there is a sort of happy-go-lucky choice performed by a committee of gentlemen selected from hospital and college staffs, assisted by, it may be, a few members from the general governing body. At each election period the names of recently-qualified students and of all those of older standing who have put their names on the list of candidates, are considered, and the history of each during his student career is read and weighed. The most distinguished men are, as a matter of course, immediately allotted to the most-sought-after posts, and then comes the question of selection out of a number of equally deserving candidates. It is now a rare occurrence for the number of these to be less than the number of posts to be filled, although such an experience is not wholly unknown at one or two of the least popular metropolitan hospitals. In the absence of other means of judging individual merits, a personal canvass among the electors is naturally set up, each having one or more names to urge, accordingly as he has had acquaintance with their owners while working in class or ward. Appointments made under these circumstances are neither satisfactory nor just, and we believe that students would be among the first to hail a change which would obviate the necessity of any such proceeding.

The most popular change of the kind would undoubtedly be the establishment of special tests, by which the merits of different students could be ascertained. The littlenesses of examinations could be easily eliminated by making the test one of a practical nature, and by spreading it over a space of time sufficient to enable the least ready to cope with those most efficient in the use of the pen. It is a matter of constant surprise in hospitals that "brilliant" men even, who have carried all before them in examinations for prizes, and who have been regarded as marvels of information, often fail miserably when called upon to discharge the duties of house-surgeon, or of house-physician. Frequently they are the inferiors of fellow-students whom they have distanced by immeasurable lengths in competition for paper prizes, when the practical side of their nature is called into requisition, and it cannot be denied that in these circumstances they are infinitely less serviceable to the patients in their charge. The fault, however, is less their own than that of the artificial system of education encouraged and fostered by regula-

tions like those now in force at many of the more prominent examinations. These demand the wide reading of books rather than extended reading of disease as it is to be seen; and often enough the most practically educated men are "referred" because they have described what they saw rather than what has been written. This spirit should not be permitted to influence house appointments in hospitals. It does, however, at present, and thus many thoroughly practical and well qualified men are debarred from realizing the dream of their student days for an unjustifiable and unreal reason.

The surgeon or physician under whom each man has worked is the proper judge of his capabilities and deserts. He it is who can best decide how far he is likely to do good or ill when placed in a position of responsibility; and were it customary to leave the selection of his deputy in the house to himself, it would be a matter of the utmost moment to him to appoint the student who most fully realized his conception of a faithful worker. The suggestion of undue influence in selections thus made is unworthy of being entertained; by adoption of the system generally it would be at once negatived, for each senior official would thereby be constituted an examiner of the candidate, who would practically, while under him as dresser or clerk, be competing for the honour of subsequently serving him in the capacity of resident assistant. We know of several recent instances where appointments have been made in direct opposition to the wishes of surgeons or physicians, opposition not, of course, expressed, but none the less real, and arising from consciousness of utter unfitness of the candidates as determined during their tenure of ward assistantcies. In fact, there are many indications pointing to the need for a radical change in the mode of electing to resident posts in hospitals, and we shall be glad to have the opinion of others on the subject.

THE PROVIDENT DISPENSARY SYSTEM.

THE Manchester Medico-Ethical Association recently adopted a resolution "to inquire into the present working of the Provident Dispensaries in Manchester and Salford," and in compliance therewith issued a series of questions to the medical profession of Manchester and Salford. The report is divided into—1. The class of patients admitted; 2. The influence of a newly-established provident dispensary on the practice of medical men; 3. The remuneration received by the medical officers of these dispensaries for their services. According to the rules of the Provident Dispensary Association—"The members shall be artisans and others, in receipt of weekly wages, whose average earnings do not exceed 30s." The evidence received, however, unmistakably points to the conclusion that persons are freely admitted as members who have no claim whatever to a participation in a provident dispensary scheme. Thus, among many others reported as members, there are shopkeepers, tradesmen, engine-drivers, pawnbrokers, and licensed victuallers, whose incomes are certainly above the limit of 30s. a week. As illustrations may be taken—A butcher, doing an excellent trade; a draper, large established business; a

pawnbroker, apparently doing well; a beerhouse-keeper, rent £25, good trade; a keeper of a coal-yard, owns house property. Amongst others who have been canvassed by an official to join, there are—A bootmaker, pays £46 per annum rent; a publican; a man who has two large shops; and a person earning £5 per week. One medical officer writes:—The collector is supposed to make inquiries into the means of the applicants for membership, but he is paid by results. I never knew but one family refused admission to the dispensary during a period of five and a half years. The collector, whose duty it is to inquire into the means of the applicants, is also the canvasser, and is paid according to the number he can induce to join the dispensary. In some dispensaries no check whatever seems to be placed upon the doings of this official; it is clearly to his interests to enrol the more well-to-do, who can pay more readily than the poor, and, consequently, he too often passes by the courts and side-streets, and confines his canvassing to the well-to-do shopkeeper and publican in the main thoroughfares. In other dispensaries it appears that the income of each member is entered in a book, which is subjected to the inspection of the committees, and sometimes, at the instigation of the medical officers, unsuitable members are eliminated. In other instances, committees, whose interest it also is to keep up the number of members, wink at abuses, or refuse to interfere. In one of the most recently established dispensaries, from which some very flagrant cases of abuse are reported, there is no committee, and almost all classes have been canvassed and allowed to join. Here may be noted the frequency with which some members leave the dispensaries a short time after admission. Thus, one dispensary, with 1,900 members on its books at the commencement of the year, and 2,100 at the close, admitted 910 new members, and lost 653, or nearly one-third. In some measure this is perhaps due to the members removing from one locality to another, but chiefly to their joining when sick and leaving as soon as they have recovered from their illness, finding it cheaper to pay the 5s. entrance-fee and 1d. per week afterwards than to call in the services of a medical man in the ordinary way. One medical man reports "that every patient he has in the district has been canvassed to join the dispensary, some of them over and over again." Another writes:—"In my own case, the opening of the ——— Provident Dispensary reduced my practice to one-half, taking away shopkeepers and beerhouse-keepers, and leaving me all the very poor." Another—"that the effect upon his practice has been ruinous; that his practice in the district of the dispensary has been reduced to *nil*, and he has had to remove to another district." Another—"that his practice has been reduced by one-fourth." As regards the remuneration received by the medical officers of the provident dispensaries, the statistics of the Dawson Street Provident Dispensary may be taken as an example. Last year the two medical officers attached received £250 between them. They paid 6,640 visits, and saw 8,510 patients at the dispensary. For these attendances 16,100 prescriptions were prepared. There were about 2,000 paying members on the books. Thus, on an average, each member had medicine prepared

for him eight times during the year, and the medical officers were paid at the rate of 3½d. for each prescription. With the above evidence before it, the Sub-Committee arrive at the conclusion that the rule as to the admission of members is repeatedly broken. The evidence received proves conclusively that at the present time the majority of the dispensaries are being seriously abused. Little, if any, check is placed upon the collectors and canvassers, who admit any whom they can persuade to join, and are paid according to the number they admit. Objectionable circulars, with the name and private address of the medical man attached, have been distributed through the district in many ways, amongst others by supplying them to shopkeepers, for wrapping their goods in. This method of advertising has been followed up by an indiscriminate canvass of publicans, shopkeepers, and tradesmen, some of whom were being attended by their own doctor at the time. The Sub-Committee repudiates any animus against a well-managed Provident Dispensary scheme. It believes that at the present time one or two of the dispensaries are fairly well managed, and not seriously abused. The evidence, however, brought before the Sub-Committee as to the present working of the scheme proves the existence of serious evils which cry loudly for reform.

Notes on Current Topics.

The Infectious Disease Notification Bill.

THE Irish Bill on this subject, which has been framed conjointly and approved by the Irish Medical Association and the Dublin Branch of the British Medical Association, and which we printed *in extenso* in our last issue, has been introduced to the House of Commons by Messrs. Meldon, M.P., Findlater, M.P., Brooks, M.P., and Moore, M.P., and it is set down for a second reading on the 21st, but there is no chance of it coming on on that day. As we have already pointed out, it provides a practical means by which all infectious cases which could be reached by any system will be speedily notified to the sanitary authority without the imposition upon the physician of functions which would cause him to be excluded from the sick room, and improperly interfere with his relation towards his patient.

We earnestly trust that this Bill will be allowed to pass, if only as an experiment, which certainly ought to be tried before our profession is sacrificed to theory and speculation. The sticklers for compulsion on the physician ought to consider whether it is not better to countenance an arrangement which is acceptable to those who are to carry it into effect, than to attempt to force upon these workers a penal measure which can only pass after a prolonged Parliamentary contest, and will then certainly be resisted by those who are unjustly and unnecessarily subjected to these penalties.

Until the probability of success of Mr. Meldon's Bill is known, we warn the profession in Ireland to stand firm and ready to oppose energetically any measure of the pattern of Mr. Gray's Bill of last year. We hear that the

Dublin Corporation will seek to have that Bill introduced immediately, and if it should be so, the question will have to be decided by a vigorous Parliamentary opposition.

The Legality of Arbitrary Dismissal of Poor-law Medical Officers.

A MOTION was recently made in London, before Mr. Justice Fry, to restrain the Local Government Board, till the trial of the action, from carrying out the dismissal of Dr. Donahoo from his post of Medical Officer of St. Saviour's, Southwark. Dr. Donahoo claims to have a freehold in his office under statutory regulations made by the Poor-law Board, the predecessors of the Local Government Board, in 1857, and to hold his office *dum se bene gesserit*. He had filed affidavits to show that the inquiry which was made into his conduct, and which led to his dismissal, was unfairly conducted, and that it was closed without his being able to call rebutting evidence. Dr. Donahoo was invited to tender his resignation, and not doing so, a letter was sent to him from the Local Government Board, informing him that unless he resigned within seven days he would be removed from his office. The present motion was made to restrain the department from so doing. Mr. Justice Fry, without calling on counsel for the defendants, said, in his opinion, the office of the plaintiff was only held *durante placito* of the defendants, and his dismissal was within their absolute discretion. But, he added, there was another ground on which he should have refused the motion—namely, that it would be highly inconvenient, pending the settlement of the dispute, to force a medical officer upon his employers.

Thus it seems to be decided that in England a Poor-law medical officer is only a tenant at will of the Local Government Board. The decision upon the same point in Ireland in reference to the dismissal of Dr. Kenny as a "suspect" has not yet been given, the Court having given the appellants time to produce certain necessary affidavits.

The Honorary Degrees of the Queen's University.

THE last act of the Senate of the expiring University has been to grant to a number of its *alumni* honorary degrees. Great offence has been given by the selection, many of the most deserving of the graduates having been passed over, while others whose claim was less obvious have been decorated by the Senate. In the Dublin morning papers a very forcible letter on the subject has appeared. It says:—

In reading the list of degrees, the fact that most forcibly strikes anyone cognisant of the affairs of the Queen's University is the extraordinary way in which Medicine has been overlooked in the distribution of compliments. In order fully to appreciate this it must be stated that the graduates in medicine constitute by far the larger part of the *alumni* of the University and by no means the part which, through the position achieved by its members, has done it the least credit. At the end of the year 1880 the graduates in arts numbered 1,088, and those in medicine 988. From the former number must be subtracted 133 who were graduates in medicine as well as in arts, leaving a total of purely arts graduates of 955, and of medical graduates of 988; and yet, in proportion to these numbers, look at the few honorary degrees that have been conferred on the medical graduates. Out of 87 honorary degrees, only 11 have been conferred on medical men,

and of these but 5 are on persons engaged in practice, the other 6 being gentlemen who are by their positions excluded from medical practice. All of the 11 are either officially connected with the University or have been so, and not one single distinction has been offered to any of the numerous gentlemen who hold distinguished positions outside the University, which has been anything but an *Alma Mater* to them.

On one matter the Senate may be congratulated—namely, the art of taking care of their own household—for, not contented with ignoring the principle of conferring the honours at their disposal as broadly as possible, nor with giving them exclusively among their own professors and examiners, they have given to each and every one of themselves who had not before been decorated—with the exception of one gentleman, a commoner, and a few persons of high rank, who presumably do not care for such things—an honorary degree. The delightful novelty of the members of the Senate acting with this brotherly reciprocity, and conferring the accolade each on the other is indeed pastoral and beautiful, and would be amusing were it not a ludicrous preliminary to the execution of a University which would more fitly have died without affording cause for a gibe.

There is a great deal of force in this protest, and all the more because it is so temperately expressed. We think that the Senate has besmirched the honours which it conferred by excluding those from them who had an obvious claim to recognition, and we regret that its last act should have been an ungracious one, and calculated to dull the memory of the University as an institution which recognised merit alone as the title to distinction.

Drafts of Troops to India.

FOR many years back the system of sending large bodies of young lads as soldiers to India has been protested against by all officers, military as well as medical, who have themselves had practical experience in our great Eastern dependency. On active service it was found that, as during the wars in Europe connected with the French Revolution, young recruits served only to fill the hospitals and occupy all available "sick transport," thus diminishing that which could be utilised for the requirements of the wounded in battle. And not only on active service was the unsuitability of young men apparent. It was equally so in times of peace, and when no further calls upon their physical endurance were demanded than the performance of the ordinary routine duties of garrison life. Even under the latter circumstances it was found that during the hot and rainy seasons the young lads thus sent out were prostrated in a relatively large proportion by the endemic diseases of the country, more especially fevers and affections of the bowels. In not a few instances a combination of these affections existed in the same individual, and in such cases a *name* was applied to the mixed affections in accordance more with theories in favour in England than with the actual nature of things. There is at least some hope that this state of matters is about to undergo some degree of improvement. Thus, according to orders recently issued by the Horse Guards, the selection of non-commissioned officers and men to proceed with batteries and drafts to India and all tropical stations will in future be made in accordance with the following conditions, except in cases where special authority may be obtained to the contrary:—1. Non-commissioned officers with four years' service unexpired; 2. Men in second,

third, and fourth year's service; 3. Men in first year of service who will be twenty years of age at date of embarkation, and who have completed three months' service; 4. Men (short service) on fifth year of service, willing to extend under General Order 80 of 1881, and article 566, Royal Warrant, June 25, 1881, with £2 bounty; 5. Men (long service) under six years' service; 6. Men (long service and re-engaged) up to 15 years' service.

That such an order as the above should be issued indicates how closely linked are questions of medical details in regard to ages during which liability to particular forms of disease is greatest, and questions which bear directly upon military efficiency of our soldiers.

Irish Butter.

ACCORDING to the *Grocer*, there never was such a scarcity of butter in Ireland as there is at present. In former years both farmers and merchants held stocks for the months of January, February, and March. But last season was so disastrous that very few could keep any stock of butter on hand, and it is now discovered on the appearance of any demand that there are no supplies to meet it. This bareness of the Irish markets is shown by the fact that large quantities of Danish and American butter and butterine are being imported for local consumption. Add to this neglect of a natural industry, that a great proportion of the butter made in Ireland is almost uneatable. It is made up in "lumps" by the small coters, who have only one cow, and therefore have to keep the cream or milk until it is semi-putrid, to churn it in a filthy cabin full of turf smoke, and fetch it to market some days afterwards, by any means available. One of the chief amendments of the Irish system must be the establishment of butter factories.

The Prospects of Medical Reform.

THE Medical Acts Commission met at 2 Victoria Street, Westminster, last week. Present—The Earl of Camperdown (Chairman), the Right Hon. W. H. F. Cogan, the Master of the Rolls, the Right Hon. G. Sclater-Booth, M.P., Sir William Jenner, Mr. Simon, C.B., Professor Huxley, Dr. Robert McDonnell, Professor Turner, Mr. Bryce, M.P., and Mr. John White (Secretary). The Commission will meet again next week, and we hear that, having pretty well settled their recommendation respecting reconstitution of the Medical Council, they will be engaged in maturing the conjoint examination schemes. It is to be feared that there will be a division in the Commission on this subject, the Scotch members taking up a strong position of opposition.

King and Queen's College of Physicians in Ireland.

At the last meeting of this College, Dr. Arthur Wynne Foot was elected a Censor of the College in the room of the late Dr. Reuben J. Harvey. At the same meeting, the College resolved to take the opinion of eminent counsel as to the legality of the following resolution of the College, passed on February 21st, 1868, namely, "That in future no King's Professor in the School of Physic shall be allowed to hold an appointment as medical officer to any clinical hospital other than that of Sir Patrick Dun."

The Working of the Army Medical System.

THE *United Service Gazette* continues to receive from various quarters complaints of the very unsatisfactory working of the new system of doctoring for the Army. Under the old plan every soldier had, as it were, a personal attendant in the surgeon of his regiment, whose undoubted duty it was to attend to all the men in the corps, under any circumstances whatever. Now, however pressing a case might be, the patient must be removed to the nearest station hospital before he can obtain any medical treatment. A case in point happened the other day. A trooper in a cavalry regiment was taken ill on parade with what looked very much like sanguineous apoplexy, a disease that of course requires immediate treatment; but the surgeon-major appealed to declined to treat the man on the spot, but ordered his removal on a stretcher to the nearest hospital. All this took time, and in the meantime the sufferer might have died for want of the relief a lancet would have given him. Fortunately, the captain of the troop was a practical man, and the trooper recovered on the application of a few common-sense remedies. But the result might easily have been fatal. Indeed, in a recent case at Aldershot, the coroner's jury appended a rider to their verdict, that the present system of putting impediments in the way of soldiers receiving medical treatment is most unsatisfactory. It is among the many changes for the worse which have been made in the Army in the teeth of all practical experience.

The Irish Union Officers' Association.

THE non-medical officers of unions have joined in organising an association to represent their views and interests, especially in relation to superannuation, and have established such a society, and are seeking from the officers the necessary funds to carry on the business in hand. With this object they have issued a circular, not only to clerks and masters of unions, and other workhouse officers, but to the medical officers also, asking them to subscribe £d. in the £1 on their income to the objects of the Association.

We have been asked by several medical officers whether they should comply with this request, and, in reply, we would say that there cannot be the least objection to their doing so, so long as the contribution does not interfere with their subscription to the Irish Medical Association, which originated the movement on behalf of the medical officers, has worked it for years, and is now busily urging it on the attention of Parliament. The bill promoted by the Union Officers' Association and the memorial presented by it to the Chief Secretary are, in fact, the bill and memorial of the Irish Medical Association, copied almost *verbatim*, but without acknowledgement of its source, from which it will be evident that the two Associations are working together for the same object. We trust they will continue to co-operate harmoniously, but we do not think it either quite fair, or at all calculated to promote the *entente cordiale* between the two bodies, that the non-medical Association should proceed to canvass the members of the medical Association for subscriptions which, if given, must necessarily, in

some instances, be withheld from the medical organisation. We, therefore, advise all Poor-law medical officers in Ireland to subscribe first to the Irish Medical Association, and, if they can afford it, afterwards to the new society whose circular they have received, and, in any representations they may make to persons of influence to support the bill, to give the Irish Medical Association the credit of having started the movement, worked out the bill, obtained the approval of Government, and constructed the memorial upon which that approval was given.

Unqualified Practice.

At Dairycoates, near Hull, recently, a coroner's inquiry was held into the deaths of two children, from the administration of some irritant poison unknown. The chief interest of the case is in the fact elicited at the inquest that the deceased had been attended by an unqualified practitioner, a chemist named Cartwright, and who, by arrangement with a Dr. Jackson, acted as assistant to the latter on terms which secured half the fees received to him, but which admitted the unqualified man to take charge of cases on his own responsibility, while exacting payments for services rendered in the name of his employer. The words in which the coroner marked his disapprobation of the whole affair very properly express the view that should be taken of it. He stigmatised it as a most improper proceeding, and continued: "It was neither more nor less than an evasion of the law. It was a matter of regret that people should be so foolish as to call in persons not properly qualified to attend them. No matter what Mr. Cartwright's experience had been, he was acting in a manner in which he was not qualified to act. He had tried to persuade them that all he did was under Dr. Jackson's instructions, and a still more unfavourable aspect of the case was to find from such a quarter that there should be a division of profits. He thought that was anything but creditable. It was most pitiable to see that when this unqualified man was called in to attend the children, he took down a bottle of worms, like a quack doctor, and said to the father, 'That is what they have.'"

We take it this case is likely to do considerable good in creating a distaste towards unqualified practitioners in the neighbourhood of Hull, especially since neither in treatment nor in diagnosis did the associated practitioners agree with the opinions uttered by disinterested physicians.

The New Oban Sanatorium.

CONSIDERABLE progress is now made with this extensive building, and the magnificence of the situation is thus being gradually realised. We speak from a personal knowledge of at least six of the countries of Europe, and we assert with confidence that in very few, if indeed in any instance, a situation so unrivalled as that of the Oban Hydropathic Establishment exists. The view from the Alhambra is undoubtedly grand; it is a view of a vast and fertile plain through the bosom of which two beautiful rivers meander, and the situation is hallowed to the student of history and human nature by the cruel fortunes of its former possessors. The view from the Oban Hydropathic Establishment, if less extensive, em-

braces beautiful lochs, as well as everlasting hills—those silent witnesses to the inscrutable something behind nature which man would, but never can, comprehend. When the mildness of the climate of Oban, even in winter, and the magnificence of its surroundings become to a greater extent appreciated, we are satisfied that it will become a favourite health resort, and we feel persuaded that its Hydropathic Establishment and Sanatorium, if properly conducted, will become a decided attraction towards this end.

Appointment of M. Charcot to the Chair of Nervous Diseases.

HAVING made for himself a world-wide reputation whilst occupying the chair of pathological anatomy, M. Charcot has entered upon another field for the exercise of his industry. He has resigned the chair of pathological anatomy, and accepted that of nervous diseases. The vacancy caused by this change has been filled up by the appointment of Professor Hayem, teacher of therapeutics, to the chair of pathological anatomy, recently held by M. Charcot. M. Hayem is well known by his works, and his appointment has given general satisfaction to the profession in France. He has a formidable task before him, from the fact that he has to follow such a man as M. Charcot. This transference of a professor from one chair to another has its advantages and disadvantages. It remains to be seen whether, in this case, medical science will gain by the mutation.

Sanitary Dangers in High Places.

ONE more lesson has been taught us with respect to the dangers incurred by clumsy or insufficient drainage in dwelling-houses, and general satisfaction will be felt that the warning has been acted upon in time to save the life of the Duchess of Connaught. The explanation of Her Royal Highness's sudden removal from Bagshot to Windsor, within three weeks from her accouchement, is found in the fact that a constant stream of sewer-gas has been entering the house at Bagshot through an open pipe leading from the main drain to beneath the central hall of the mansion. For some days an unpleasant smell had been manifest in the vicinity of the pipe, and the royal convalescent appeared to be developing symptoms which could only be ascribed to some such influence. Immediate removal from the tainted atmosphere was counselled at a consultation of the Duchess's attendants, and since this has been effected the patient has made the most satisfactory progress towards complete recovery.

We trust this discovery will be accepted as an indication of the searching examination necessary to be made ere any house, however well arranged it may be considered, can be said to be a safe dwelling place. So long as sanitary engineering fails to be carried out with the precision and exactness its importance demands, so long will there exist danger of serious defects in drainage and ventilation being permitted to pass unnoticed. There is too much reason to fear that Dean Stanley's valuable life was sacrificed to inefficient construction in this respect. We cannot afford to let the lesson taught by his loss pass unheeded.

Aneurism of the Arch of the Aorta.

At the Clinical Society on Friday evening an interesting discussion ensued on a paper read by Dr. Finlay, in which he described a case of aneurism of the ascending part of the arch of the aorta. The principal point in connection with it was that relating to the desirability of operative interference; and the especial question in most speakers' minds seemed to be whether or not galvanopuncture might be safely employed. There is a good deal of sound sense in the remark made by Mr. Parker, to the effect that much of the disappointment hitherto experienced in electrolytic operations may be due to defects in the apparatus employed. This is strikingly shown in a case we recently referred to as reported in an American contemporary. In it the current had been supposed to act for nearly half an hour, and some consolidation certainly occurred; but examination of the apparatus showed that for most of the time at least it was impossible that any current could have been passing. If, as Mr. Parker recommends, improved instruments, and batteries equally improved are employed in future experiments on aneurisms, we may not unlikely be able to record much more valuable results of galvanopuncture.

In connection with the same subject, we may remind Dr. Finlay of a fact first published at the Clinical Society, that, viz., by very largely diluting iodide of potassium it may be given in any amount without producing a single ill-effect.

Medical Bills in Parliament.

In the House of Commons on Tuesday week, Sir Trevor Lawrence gave notice of the Bill to amend the Medical Act, 1858, formerly known as Lush's Bill; Mr. P. Taylor gave notice of a Bill abolishing the compulsory clauses of the Vaccination Acts; Mr. Reid, a Bill for the total abolition of vivisection; and Mr. Stansfeld, a Bill for the repeal of the Contagious Diseases Acts.

The Grand Prix Lecaze.

The Paris Académie des Sciences has awarded the Grand Prix Lecaze, of the value of £400, to Professor Brown-Séquard. The honour thus conferred on the eminent recipient of it is perhaps the highest in the power of any Association to bestow, since it is given only for long-extending devotion to physiological science, and then only when it has resulted in important discoveries. The services of Brown-Séquard have indeed been of a nature that renders any recognition of them, however high, no more than their author has established a thorough right to receive. As an investigator he stands second to no living physiologist, and even the former recipients of the prize just awarded by the Academy, Chauveau, Marey, and Daresse, have scarcely so well founded a claim to the honour. It is not too much to say of Dr. Brown-Séquard that his devotion to science has been of the most disinterested description, since he has undoubtedly resigned, on account of it, a position in the line of medical practice that would compare with that of the most successful of modern practitioners. Every member of the profession will feel that Dr. Brown-Séquard has been appropriately honoured by receiving this proof of the estimation in which his achievements

are held, and will wish him long years in which to enjoy the distinction and yet further extend the labours which have made him world-famous and universally respected as a light of modern science.

Ovariectomy in America.

DR. JOHN HOMAN contributes to the *Boston Medical and Surgical Journal* for January 26th a tabulated statement of the result of thirty-two ovariectomies performed by him in the year 1881. Of these three died, death being caused in one case by exhaustion, the tumour removed having been very vascular, and nearly solid. In another case acute mania set in on the eighth day after operation, and as there were no post-mortem indications to show any untoward occurrence in connection with the wound, and as insanity was hereditary in the patient's family, the case may be fairly set down as one of death from non-preventible causes. In the third fatal case the outer surfaces of the tumours—both ovaries having been removed—were of a brown colour, and beginning to decay. In addition to the thirty-two cases of completed ovariectomy, Dr. Homan made exploratory incisions in three instances, and after thoroughly investigating the tumour, closed the wound, and in each case all subsequently went well. Dr. Homan adds also that he has done colotomy successfully, making the permanent opening in the pubic region. The ages of his ovariectomy patients varied from eighteen to seventy-three years, recovery having ensued in the case of both these extremes. The length of incision made was generally four or five inches, but sometimes it was extended to as much as seven, and in one case (death) eight inches. Taken altogether, however, the results are very good, and reflect much credit on the operator. The pedicle was invariably tied and burnt off with Paquelin's thermo-cautery. No mention is made of antiseptics.

Paul Bert and the Chair of Pathological Anatomy.

ON the 26th January Paul Bert virtually ceased to be a minister, as the fall of his leader then took place; but on this date his last official action was one to provoke the Faculty of Medicine. Charcot had resigned the Chair of Pathological Anatomy, Professor Hayem had been selected to fill it by the Faculty, thus only changing his chair. Notwithstanding this decision of the Faculty, in the *Journal Officiel* appeared an announcement that the Chair of Pathological Anatomy was vacant. There is some indignation at this act of the Minister of Public Instruction, as it over-rides the privileges of the Faculty of Medicine; and it is to be regretted that the distinguished pathologist, before publishing his order, did not consult the Dean. Professor Hayem is worthy of following Charcot. M. Paul Bert does not, surely, think of filling the Chair himself!

ACCORDING to M. Paul Bert (*Journal de Thérapeutique*) special venoms are secreted by the toad, salamander, newt, frog, &c. From the glands on the neck of the frog he has collected a liquid which, if injected into a sparrow, occasions death with convulsions, the heart being arrested in systole.

The Sanitary Benefits of Industrial Dwellings.

DURING the last half-year the Newcastle Industrial Dwellings, which contain an average population of five hundred persons under one roof, exhibited the low average death-rate of eight in the thousand; the birth-rate during the same period reached the average of forty-two in the thousand. These results are the more satisfactory when it is considered that this block of dwellings is situated in the lowest part of the town, and is inhabited exclusively by the work-paid section of the industrial class, and labours under local disadvantages from which most of the London Improved Dwellings are exempt.

"Vaccination" for Diseases.

Is it the case, after all, that the method of inoculating persons with diseased matter other than that of vaccinia or small-pox, whichever it may be, is not new? There is reason to believe that such really is the case. At page 34 of a report recently submitted to the Governor of Ceylon on the subject of a disease, or combination of diseases, known as "Parangi," the following statement occurs:—"On the question of inoculation which is practised in Africa and the West Indies by the negroes on the estates, to acquire yaws and to escape work, allusion is only made by Mr. W. D. Wright, when Government Agent of the North Western Province of Ceylon, in his Administration Report for 1871 he says:—"When reading a few years ago Dr. Looss's report about Parangi, I do not remember having seen any notice of preventing the sad consequences of the disease by a species of inoculation, and will therefore describe the practice in the remote parts of the Vanni district. It is to make children, when they are about one year old, partake of rice off a leaf or plate on which a person suffering from the disease has eaten. In a short time pustules like itch appear on the child's body, and then medicines containing minute quantities of mercury are administered, which cause the pustules to dry up in seven days, the scales to fall off, leaving deep dark marks, which in course of time disappear. It is said that this is an almost certain prophylactic, and that though the disease may attack one who has been so guarded, the effects are never serious."

Unfortunately, the above are the only details we are able to obtain regarding inoculation for yaws and for parangi. The former of these diseases is believed to have no connection with syphilis; the latter, however, is by some writers considered to be made up in part of tertiary syphilis, but neither yaws nor parangi appear to be susceptible of transmission to animals. It is hoped that some of our readers may be able to give further particulars on the subject thus broached.

OWING to the extraordinary mildness of the winter and scarcity of rain in Spain, the mortality has increased nearly 50 per cent. in the Spanish capital; and small-pox has now developed into epidemic form, causing over 200 deaths in January, and 150 patients suffering from that disease are now in the principal Madrid hospital alone.

Guiteau's Head.

THEODORE MILL has taken a mould of the head of the assassin of General Garfield. It was not easy to obtain the consent of Guiteau to the operation, as it involved the shaving off of his beard. The sculptor, however, persuaded him to acquiesce by mentioning the names of the illustrious men, casts of whose heads he had taken. Guiteau smiled with complacency at the thought of the fame in store for him (Madame Tussaud's studio of *celebrities*!)

Guiteau's head measures $23\frac{1}{2}$ inches in circumference; phrenologically the bump of esteem measured $6\frac{1}{2}$ inches; that of firmness $6\frac{1}{2}$ inches. The left side of the head is well developed, and apparently normal; the right is almost flat. The sculptor declared that he had never examined a head so peculiarly formed.

Touching Guiteau, we are informed by a French exchange that some American insurance companies accepted policies on his life whilst he was in the dock. The enterprise of American offices is well known, but "the height of assurance" has here reached a point to which few English offices would aspire. Supposing this is true, we can only imagine that the policy taken out has been for some small sum—£100—and that the object has been to advertise the office which undertook the risk.

Modern Surgery.—Extirpation of the Lungs.

IF the ancient masters of surgery were now to visit some of our modern hospitals, and saw the operations therein performed under the protecting shadow of antisepticism, what surprise would they not evince at the daring of modern surgeons! Operations condemned in their day as unjustifiable and hazardous are now recognised standard ones. They would learn with surprise that we remove kidneys, spleens, uteri, portions of intestines, larynx, with perfect *insouciance*. It is even now proposed to extirpate one of the lungs. At a recent meeting of the Biological Society of Paris, M. Marcus (Jassy) suggested an operation for the removal of one of the lungs. M. Marcus believes that, as the lungs are dual, one could be removed; the other would do the work, just as one kidney does the work of two, when one has been removed. M. Marcus has put his suggestion to proof. He extirpated the right lung in some rabbits and dogs. In spite of antiseptic precautions, they, however, died. The dogs died rapidly; the rabbits lived for three weeks. M. Marcus thinks that his results are encouraging.

IN the large towns last week the highest annual death-rates per 1,000 from scarlet fever were:—3·8 in Brighton, 3·6 in Hull; from whooping-cough, 5·4 in Wolverhampton, 3·8 in Brighton, and 2·9 in Bolton; from measles, 3·9 in Blackburn, and 3·5 in Norwich; and from "fever," 1·6 in Preston. Eleven more fatal cases of scarlet fever were recorded in Hull, making 712 that have occurred in this borough since the beginning of July last. The 34 deaths from diphtheria included 18 in London, 7 in Portsmouth, 2 in Brighton, 2 in Liverpool, and 2 in Salford. Small-pox caused 15 deaths in London and its suburbs, 1 in Nottingham, 1 in Bolton, 1 in Liverpool, and 1 in Leeds.

Prosecutions against Unlicensed Dentists.

THE Branch Medical Council for England has granted the necessary permission to prosecute two persons, named Smith, of Praed Street, and Valleck, of Edgware Road, London, for illegally practising as dentists, they not being registered.

DR. MICHAEL O'BRIEN, of Miltown Malbay, co. Clare, an M.D. of the Queen's University, has been arrested and sent to prison.

DR. KENNY, lately Medical Officer to the North Dublin Union, who was incarcerated as a "suspect" some months ago, and dismissed from his office by the Irish Local Government Board, has been set at liberty in consequence, it is understood, of the ill-health of his family.

We understand that the War Office has appointed Surgeon General J. S. Furlong, M.D., to be Principal Medical Officer to the Forces in Ireland. Dr. Furlong, who served throughout the Crimea and Indian Mutiny campaigns, has been recently serving as Principal Medical Officer in Canada.

THE death of the venerable Dr. George Samuel Jenks, formerly physician to the Sussex County Hospital, Brighton, at the great age of ninety-three, is announced as having occurred at Bath, on the 7th inst. The deceased, who took his M.D. degree at Edinburgh in 1820, was in early life an army surgeon.

A BUST of the late Dr. Robert Smith, Professor of Surgery in the University of Dublin, and for many years Honorary Secretary of the Dublin Pathological Society, has been executed at the cost of the members of that Society, and presented by them to the Irish College of Surgeons, where it has been placed amongst the series of busts of distinguished Irish surgeons which decorate the Hall of that College.

AN address, accompanied by a handsome silver salver and purse of sovereigns, were recently presented to Dr. Aickin, of Belfast, on the occasion of his recovery from a severe illness, and as a token of the esteem in which he is held, and to record his high professional skill. The salver bore the following inscription:—"Presented, together with a purse of sovereigns, to William Aickin, Esq., M.D., by his friends and patients. Belfast, 1882."

IN the principal foreign cities the rates of mortality per 1000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 25, Bombay 31, Paris 30, Geneva 28, Brussels 23, Amsterdam 21, Rotterdam 31, The Hague 29, Copenhagen 26, Stockholm 22, Christiania 32, St. Petersburg 50, Berlin 23, Hamburg 24, Dresden 23, Breslau 30, Munich 32, Vienna 28, Prague 29, Puda-Pesth 40, Naples 33, Turin 26, Venice 31, Alexandria 38, New York 32, Brooklyn 26, Philadelphia 23, Baltimore 26. No returns were received from Madras, Rome, and Lisbon.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

GLASGOW UNIVERSITY MEDICAL BALL.—The annual ball of the students attending the medical classes at this University was held on the 9th inst., in the Queen's Rooms. There was a large attendance, and the assembly was patronised by several of the medical professors.

BATHGATE.—THE LATE DR. KIRK.—The funeral of Dr. James Balfour Kirk took place on the 9th inst. at Bathgate, amidst tokens of universal mourning. The shops in the town were closed, and in many of the collieries and public works business was suspended. A large company followed the body to the cemetery. The Provost and magistrates, with others, met in the Court Hall and walked to the church, where religious services were conducted by ministers of various denominations. Dr. Kirk has been well known in Bathgate for the last thirty-three years, and out of a lifetime of fifty-five years he had devoted thirty-four years to the medical profession. During the thirty-three years that Dr. Kirk spent in Bathgate he was held in high respect.

EDINBURGH HEALTH LECTURES.—Lectures specially advertised for men, or specially for women, seem decidedly successful, and when unusual details are expected there is a rush. The special lecture for men, at Edinburgh, on Saturday, the 4th inst., attracted such a crowd, that the reserved portion of the Hall was invaded, and many members of the Society were consequently prevented from obtaining seats. Under those circumstances, Mr. Annandale consented to re-deliver his lecture on Saturday, the 11th inst., when the crowd was not quite so great.

THE CHAIR OF PATHOLOGY IN ABERDEEN.—The deed of foundation of the Erasmus Wilson Chair of Pathological Anatomy in the University of Aberdeen has been signed by Sir Erasmus, the donor. The patronage is to be vested in the Crown, and the deed has been received at the Home Office. One of the conditions is, that the Professor shall not engage in practice. The endowment is the free annual proceeds of £10,000. We believe that, besides the sum so liberally given by Sir Erasmus Wilson, there is already a considerable sum raised by private subscription, which will greatly add to the emoluments of the chair. Dr. J. D. Hamilton, of Edinburgh, will, we believe, become a candidate. Dr. Hamilton is a pathologist pure and simple, and has all the energy and enthusiasm which go to make a successful teacher. Aberdeen is comparatively a young medical school, and if mindful of its future, should add to its staff men like Stirling and Ewart, ready and anxious to add to the glory and honour of the University. We are sure that Dr. Hamilton would not betray the trust placed in him.

SIR ROBERT CHRISTISON'S SUCCESSORS.—It is understood that Dr. Balfour, Emeritus Professor of Botany in the University of Edinburgh, will be proposed as successor to Sir Robert Christison in the office of Assessor of the General Council in the University Court. At the Royal Edinburgh Hospital for Sick Children, Sir Robert's appointment as Consulting Physician has been conferred on Dr. R. Peel Ritchie, F.R.C.P.E. Dr. Ritchie has been long connected with this Institution, and well deserves the honour conferred upon him.

THE ROYAL INFIRMARY, EDINBURGH.—A stranger visiting this institution would notice with surprise that the ceilings of several of the corridors are under repair, and if inquisitive enough to ask the reason, would be informed that the "dry rot" had made its appearance in the building. For his further

information he might be told that during the building of the Infirmary the committee were favoured with anonymous letters informing them that the contracts were not complied with; and that the committee, acting on the suggestions of the writers of the letters, consulted some high authorities at great expense; that on the statements made by those high authorities they acted, with the result that a portion, if not all of the Infirmary, will have to be refloored at great expense. We do not see that under the circumstances the committee are to blame; they did their best, but there cannot be a doubt but that heavy responsibility rests somewhere and on somebody, and that it is most unjust to saddle the already scanty resources of the Infirmary with a debt for reflooring.

Literature.

SIBSON'S MEMOIRS. (a)

The importance of many of the late Dr. Sibson's contributions to medical anatomy might be taken as ample justification for the publication of the less easily accessible papers over which their author spent such loving care. The volumes, however, into which Dr. Ord has collected the monographs scattered in various "Transactions" and periodicals, will serve a higher purpose even than that of informing a younger generation of the grounds on which many of the conclusions daily taught them in the wards have been founded. They will act as a constant memorial of one whose activity of mind and unswerving industry cannot fail to be apparent to every reader of his works, and also to influence others in the way of steadfastly emulating the example so worthily set. In this connection, too, we hail with satisfaction the sketch of Sibson's life prefaced to vol. i. of the series, and which, marked as it is by graceful appreciation of the character it attempts to portray, is written with a happy freedom from unwholesome adulation, while breathing at the same time even enthusiastic admiration that cannot fail to create a fitting regard for its subject in those to whom he was personally unfamiliar.

Of the papers included in these reprints, the most important are probably those dealing with changes in the structure and position of internal organs brought about by varying conditions of life, and the bearing these have on the well-being of the individual, both in health and in disease. The amount of careful observation evidenced in these papers will be at once appreciated, and the suggestiveness of their contents is hardly to be over-rated. The pages, for instance, dealing with the conditions of the lung in diseases affecting its bulk and position, can be read by no one without affording him a fund of invaluable information on the subject of chest complaints and the methods of dealing with them. And similarly with the matter of the third volume, which treats of changes in the situation and form of the heart and great veins. This portion of the work, indeed, is already generally familiar to medical readers, from its having been originally contributed to Reynolds's "System of Medicine," but, notwithstanding, we think Dr. Ord has wisely included it in the present collection.

In the second volume are included six papers dealing with the subject of respiration. The movements of respiration in health and in disease are carefully analysed, and the causes which excite and influence the process in both conditions are investigated; the last two essays are respectively devoted to gastro-intestinal distension and enlargement of the liver, and to a consideration of the influence of distension of the abdomen on the functions of the heart and lungs. These essays, like most of the others, are reprinted from sources not easily to be got at in the present day, and sufficient thanks can hardly be given for the opportunity thus afforded of obtaining ready access to them. Dr. Sibson's instructions for measuring the chest, and the description of his machine invented for obtaining accurate records of the dimensions of the thorax, are contained in this volume (ii.). "Pericarditis," the essay contained in Reynolds's "System," will be found in the third and fourth volumes of the collected works, and the latter is probably, from a purely medical point of view, the most interesting of the series. It includes the well-known article on Endocarditis, also taken from the "System"; one on the treatment of facial neuralgia by inhalation of ether, with the

(a) "The Collected Works of Francis Sibson, M.D., F.R.S." Edited by W. M. Ord, M.D. Illustrated. 4 vols. London: Macmillan and Co.

description of a new inhaler; remarks on the action of narcotics, the effects of chloroform, &c.; two essays dealing specially with chloroform, its use in neuralgia, and on the mode in which it causes death; and the address in medicine delivered before the British Medical Association in 1873. In addition, there are one or two lesser papers, and notably a lengthy tabular analysis of a large number of cases of acute rheumatism and acute gout treated by Dr. Sibson in St. Mary's Hospital from 1866 to '69. A copious and well-arranged index adds greatly to the value of these volumes, in presenting which to the reading members of the profession Dr. Ord has conferred a benefit not readily estimated. As an editor he has admirably fulfilled the task essayed by him. As a biographer he has succeeded in bringing before us one whom to have known was to revere, and whose influence for good will last while men continue to respect devotion to a cause and exceptional power of promoting its best interests. A more desirable memorial of Dr. Sibson's well-spent life could not be designed, and the arrangement of the volumes is well adapted to secure the aim in view in their production. They necessarily contain only a selection of the multitudinous results of Sibson's labours; but each component article is well deserving of the place it holds in the four beautiful books before us. The illustrations are well executed, and even where not specially drawn, are clear and precise. Indeed, the whole printing of the work is most excellent, and the publishers should be duly credited with the elegant appearance it presents.

Correspondence.

"THE DENTAL DIPLOMA TRAFFIC."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Taking considerable interest in the discussion of the above subject, which has occupied your columns for the last two or three weeks, I would ask you to give publicity to the following facts:—

A fellow student of mine, who has completed his curriculum for a medical and a surgical qualification, and who has practised dentistry for the last fifteen years, to my knowledge, presented himself for examination for the Irish Dental Diploma, and I now hold in my hand a note conveying the Board's refusal to examine him.

My friend, I may remark, does not come within the category of "hairdressers' assistants" *et hoc genus omne*, but is a gentleman by birth and education: I should, therefore, very much like to ascertain how it is that the College refused to examine him, with such credentials, for their Dental Diploma, whilst others, such as described by you, were received with open arms, and whilst they would not refuse him should he offer himself for their surgical qualification. To me it seems a strange anomaly.

I am, Sir, yours, &c.,

A MEDICAL STUDENT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with pain your remarks on the above subject, though I am constrained to admit you have shown great manliness and watchfulness in bringing a matter of so much importance before both professions. Hitherto, I have gone out of my way to contradict imputations brought against the Examiners of the Royal College of Surgeons of Ireland, and up to the time of your observations I advised many candidates to go up to Dublin. Not ignorant men, but men who were informed by me that they would have to go through a thorough practical examination in dental surgery and mechanics, this being my experience when I went up, and I must say it is very unfair of the Examiners to link those who have gone to the trouble and expense of qualifying themselves in their profession with an *omnium gatherum* of all the shopkeepers who choose to misrepresent themselves. It has been suggested that the R.C.S.I. are relieved of the responsibility when the form is completed, *i.e.*, signed by two qualified surgeons, and two dentists of repute. I say a grave responsibility rests with the Examiners in ascertaining the antecedents and the *bona fides* of the signatures of the candidates who present themselves; or this difficulty could be easily overcome by making it a *sine qua non* that the form of application must be signed by two members of the Odontological Society and two members of the British Dental Association. This would stop the abuse at

once, and if the Examiners lose anything by it, for Heaven's sake let us get up a subscription to compensate them for their imagined loss. So far as I am concerned, if what we hear is correct, I wish I had never seen Ireland; I could have gone elsewhere with half the trouble and expense; my only reason in going to Ireland was that I preferred to seek the College recommended by the Dental Diploma Committee, headed by my friend Mr. O'Duffy and others, who have by their unselfish labours done so much to elevate our profession. I would like to say something about the 2,500 you so properly inform us are invited to the feast, but I refrain from doing so. Surely such advertisements are not in existence; if they are, let us "keep it dark" and blush, for we know that when anything nasty is going on in the world and publicity given to it by the press, its nastiness is intensified by the direction it gives, to morbid minds, "to wallow in the mire."

Thanking you, Mr. Editor, for bringing this matter before the profession, and trusting the Fellows of the College will see their way to take up the cause so ably advocated by you,

I am, yours, &c.,

APPLEBY KING, B.A., L.D.S.I.

PROVINCIAL HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—In your issue of the 1st inst., you discuss, under this heading, the mode of electing honorary surgeons to provincial hospitals.

It may be interesting to your readers to know the method of electing honorary physicians and surgeons adopted many years ago at the Leeds Infirmary, which has worked most satisfactorily both to the candidates and the interests of the Institution.

The following is a copy of the rule:—

"23. The election of the honorary physicians and surgeons shall be vested in a special committee, consisting of the treasurer for the time being, and two members of the weekly board to be appointed annually by the said board, together with twelve governors (not being members of the weekly board) who shall be appointed at the annual general board, and one-fourth of whom shall retire annually and shall be ineligible for re-election until the next annual general board; the order of their retirement being determined in the first instance by lot, and afterwards according to seniority of election. At any meeting of such committee seven members shall be present to form a quorum, and the chairman shall not be entitled to any casting vote. In case of the death or retirement of any member, the remaining members shall constitute the committee until the ensuing general board, when the vacancy shall be supplied."

The governors selected to serve in this committee are gentlemen of the highest independence of character and not likely to be influenced by their personal friends, but who will vote for the best man, their only desire being to obtain the greatest good for the hospital.

I am Sir, your obedient servant,

T. BLAIR,

General Manager Leeds Infirmary.

WHO IS TO PAY THE DOCTOR?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—In compliance with your invitation to general practitioners to give their opinion of Dr. Lamb's case (Jan. 25th) I must say, after an experience of years as a general practitioner in a manufacturing district, that I consider Dr. Lamb perfectly justified in the course he adopted. If Dr. Lamb told the wholesale druggist from whom he obtained his drugs that he had made a bad debt, would he make him any reduction? Not he. Had he ordered beef-tea, would Mrs. Manchester have gotten beef from any butcher without the money, or would any one censure him for withholding it? Not they, indeed. It appears to me that Messrs. Alford are the culprits, if culprits there be, or else they are the people to whom Dr. Lamb should have applied for payment, as it seems that they either allowed the boy to remain in a fit without sending for medical aid (knowing if they did they would be liable) until his mother arrived on the scene, and sent herself for Dr. Lamb, or else they sent for him, in which case they are answerable to him, and Dr. Lamb should have sent his bill to them.

General practitioners cannot be too careful; they are con-

tinually being imposed upon, and do far too much, in common with the rest of the profession for nothing, so that people have come to think they have a right to the doctor's services at all times, and that he dare not refuse to attend.

I am, &c.,

Uttoxeter, Staffs.

G. P.

Royal Colleges of Physicians and Surgeons, Edinburgh.—Double Qualification.—The following gentlemen passed their first professional examination during the February sittings of the Examiners:—

John James Oakeshott, Highgate; John Fitzgerald Burke, Ennis; Charles Horace Barkley, London; Lawrence John Raymond Louis Quin, Belfast; Charles Cumberland Brodrick, Jersey; Arthur Charles Kemble, Essex; Arthur Foulds Thomas, Halifax; Richard Cody Rowan, Hamilton; Arthur Herbert Butcher, Ripon, Yorkshire; Michael Joseph Molony, Caher, Ireland; Hunter Urquhart Walker, Madras; Charles Alfred Mitchell, Dewsbury; George Easingwood Bianshard, Edinburgh; Robert Buck Carruthers, Wigton, Cumberland; John William Dunbar Hooper, Dinapore, India; John Powell, South Wales; William Macdermott, Fallymoney; John Charles King, Galway; Charles Maxwell, Lockerbie; Samuel William Brierley, Victoria, Australia. And the following gentlemen passed their final examination and were admitted L.R.C.P. Edinburgh and L.R.C.S. Edinburgh:—Hamilton Meikle, Alabama; Joseph Balfe, Dublin; Augustus William Thomas, Swaffham; George Reginald Eakins, County Tyrone; John Burdon, County Durham; Joseph Hysanth Tynan, Edgeworthstown; Walter Spencer, Yorkshire; Francis Moore, Guernsey; William Robert Allen, County Antrim; William Pennefather Warren, Queenstown; Thomas Galland Charis Heak, Derbyshire; Arthur Edward Blacker, Somersetshire; George Wis on Baker, London; George Arthur Patrick, Bolton; Frederick Anastasius Saunders, London; Marcus William Alatton Keane, Whitby, Yorkshire; John Fitzgerald Burke, Ennis; Joseph Wallace Lunnac, Donegal; Alfred Ellison Muncaster, Manchester; Adam Robert Hamilton Oakley, Highgate; George Dobson Crowther, Yorkshire; Arthur Edward Cecil Spence, Allahabad; Henry Ralph Gatley, Park, near Truro; George Jukes, Cumberland; Thomas Wild Fairman, Biggar; Thomas Aitchinson, Northumberland; George Savage Martin Baxter, Brighton; William Patrick Kirwan, Galway; Henry Hele Bate, Swansea.

Royal College of Surgeons, Edinburgh.—The following gentlemen passed their first professional examination during the recent sittings of the Examiners:—

Harry Graham Smith, Edinburgh; Frank Sturges, London; Elwes Steele, Monmouthshire; Thomas Tenison Collins, Tipperary; Frederic John Bateman, Norwich. And the following gentlemen passed their final examination and were admitted Licentiates of the College:—Charles Dundee, Bruslee, Ireland; Hormaeje Edaljee Banatvala, Bombay; George Henry Butler, Christchurch, Hauts; Archibald Clarke Robinson, County Antrim; Septimus Lowes, Newcastle-ou-Tyne; Michael Joseph Collins, Cork; James Shedden Elder, Eaglesham.

Association of Surgeons Practising Dental Surgery.—The following Fellows have been appointed this week office-bearers for the ensuing year:—President: Mr. Samuel Cartwright, F.R.C.S. Vice-Presidents: Messrs. J. A. Baker, Thomas Edgelow, Francis Brodie Imlach, F.R.C.S., S. J. A. Salter, F.R.S., and John Smith, M.D., F.R.S.Ed. Treasurer: Mr. S. Hamilton Cartwright. Hon. Secretary: Mr. J. Hamilton Craigie. Council: Messrs. Edward Bartlett, T. W. W. Fay (Liverpool), F. Fox, Peter Orphoot, M.D. (Edinburgh), W. G. Ranger, and Augustus Winterbottom.

The Cancer Hospital, Brompton.—The annual general meeting of the Governors of this Hospital was held last week, under the presidency of Mr. David Mocatta:—From the 31st Annual Report of the Committee it appeared that the enlargement of this Hospital is rapidly progressing, and when completed will contain beds for 120 patients, as well as to supply increased facilities for study. The Surgeons' Report showed that during the year, 1,030 new patients were received, 334 being in, and 696 out-patients: 105 of the in-patients underwent surgical operations, and 229 were treated by other means. It further showed that more humane and successful methods of treating the disease are gradually unfolded, and cases formerly regarded as hopeless now yield to treatment. The Rt. Hon. Earl Sydney was elected President in the room of the late Earl of Airlie. The proceedings terminated with the usual votes of thanks.

NOTICES TO CORRESPONDENTS.

23 CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. These cases

will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

THE CLINICAL SOCIETY OF LONDON.—In consequence of the authors of papers not having supplied us with the usual abstracts, we are compelled to hold over our reports of the meeting on Friday last.

PREPARATIONS WITH LIEBIG'S NAME.

It may be remembered that some time since a controversy was raging in the medical journals as to the original inventor of a certain Obstetric Bag, wherein two eminent gynecologists disputed the right of priority to certain improvements; others joined in the fray, and this wordy warfare was dignified with the name of "the battle of the bags." This time, another battle is raging over the use of Liebig's name, which is at present confined to the lay press, but as we have been drawn into the dispute and the weight of our authority solicited, we would briefly summarise the case thus:—Many years ago the original Baron Justus von Liebig, after extensive experiments, introduced to the profession and the public his celebrated "Extractum Carnis," which soon became, and is still, justly popular as a dietetic article of great value. A few years after Liebig's death, a cocoa was introduced under the style of *Baron Liebig's Cocoa*, with the sanction and pecuniary support of the second son of the original Baron von Liebig, and this has been advertised thus:—"Baron Liebig, the eminent chemist and analyst, who has invented and who superintends the manufacture and analysis of this preparation, as well as the Liebig Company's extract of meat, &c., &c." It is to this misleading statement that the present controversy is due; and it is but right that the matter should be placed on a proper footing. That the eminent chemist was the originator of Liebig's extract of meat is certain, and it is equally certain that he had nothing whatever to do with Liebig's cocoa, inasmuch as this was not brought out until several years after his death. It is therefore untrue that he invented the two articles; and it is equally misleading to call the present possessor of the name "the eminent chemist." The cocoa should be called plainly Baron Hermann von Liebig's cocoa, and no misconception could be possible.

A JUNIOR PRACTITIONER.—The course of "Lectures on Symptoms," by Dr. Roberts, terminated last week. A new course will be commenced in our next or following issue on the "Connection of Symptoms with particular Organs and Structures."

MR. L. M.—Many thanks; proof will be sent in due course.

DR. A. H. M.—The result of our inquiries is favourable to the person concerned. You have now done all that was necessary.

MR. E. J. S.—With much pleasure; send us the MS.

THE SUNDERLAND CONSPIRACY CASE.

To the Editor of the MEDICAL PRESS AND CIRCULAR,

SIR.—You will, I feel sure, excuse me when I take the liberty of thanking you most heartily for the kind and just remarks expressed in your Journal of the 1st inst. with reference to the recent prosecution of my poor unfortunate patient Mr. Michael McMann and myself by the North-Eastern Railway Company.

It is now pretty evident to all that the case, so far from being a prosecution so-called, was neither more or less than a point-blank persecution to crush me. That it was so I well know, but as I am unable, for certain reasons, to enter into details at present (though at some future time I shall take the liberty of reverting to the matter more fully), I content myself with again expressing my hearty thanks for the sympathy you have shown me.

I am, Sir, yours faithfully,

GUSTAV ADOLPH ABRATH, M.D.

Sunderland, Feb. 8th.

* * Dr. Abrath having been honourably acquitted of the charge brought against him, there is no necessity to revert to the subject, as our readers have already had the case laid fairly before them.—Ed.

A LICENTIATE.—Your qualifications are quite good enough to dispense with any question of eligibility on that score. All the important steamship companies require the services of medical men in the capacity of ship-surgeon; and although you may have to wait a little for an appointment, you should not have much trouble in procuring one that would suit your purpose. Consult Dr. Diver's useful little volume, "The Young Doctor's Future," published by Smith, Elder, and Co. It gives the regulations, addresses, &c., &c., of the principal lines.

MR. EDWARD PERRY.—We have been quite unable to make out the drift of your communication. Whether you have mistaken the statements made or not, it is wholly without reason that you should adopt the course you appear to have entered on. We cannot undertake to notice any further letter which does not contain explicit directions how the matter is to be proceeded with.

EUONYMIN.—The drug is described as a mild aperient, expectorant, and diuretic. It is being somewhat largely used in this country as a remedy in habitual constipation, and by some it is said to be of service. The dose is $\frac{1}{2}$ to 2 or 3 grains: best form, pill.

DR. B.—No. Purely as a consultant. His practice is a very large and lucrative one.

CONSULTATION ETIQUETTE.—A correspondent writes: Kindly inform me in the next number of the *Medical Press and Circular* what is the etiquette in cases of consultation—which doctor has a right to enter the patient's room first—the doctor called in or the doctor in attendance?

[If there be any etiquette in the matter, except the unwritten law, of gentlemen, or if there be any distinction made between physician and consultant, we think that the family doctor is the proper person to show the way to the new-comer.—Ed.]

DR. SUMMERS.—Thanks; we shall not fail to utilise the information when the time arrives.]

MR. THOMAS KEITH.—If the assertions made in our contemporary are deliberate mis-statements, we trust you will be successful in your efforts to trace their authorship. You may depend upon our assistance in exposing the matter when unearthed.

MR. G. WHITE is thanked for his note.

DR. HUNTER.—We cannot now lay our hand upon exchange in which the article appeared. This much we may speak with certainty: It was a New York medical journal, and the essay referred to was a very clever and humorous one, pointing out how frequently medical men were compelled to equivocate in order to conceal their own opinions; to hold out hopes when there are none, and to deceive nervous and fussy patients by giving bread-pills, placebos, &c., &c.

THE "MEDICAL PRESS" REPORT ON THE SMOKE ABATEMENT EXHIBITION.

THE following are replies to letters received on the subjects embodied in our Special Reports:—

MESSES. MUSGRAVE & Co.—If you will kindly refer to our last number you will see that our condemnation of a stove (whose name is not mentioned) forms a separate paragraph to that in which your exhibits are referred to. We certainly had no thought of referring to your stoves thus, as they appear to us to possess considerable merit from a sanitary point of view.

W. S. G. (Northampton).—Coal-fires do produce carbonic acid, but this is removed by the chimney. Gas-burners ought to be fitted with tubes for removing the products, but this is very rarely done to ordinary lighting burners, and not always to gas-stoves, hence their danger to health.

MR. FLETCHER.—Your letter shall receive attention. Gas-stoves without a fine might, perhaps, be tolerated where the ventilation is perfect, but it never is. Gas should be made to facilitate—not impede—ventilation. For this purpose all burners should be under ventilating outlets.

DR. BOND.—Your note has been forwarded.

C. G.—Yes; all gas-stoves should be fitted with a flue to carry away the fumes. Of course, the flue need not be so large as is required for coal-stoves, a 2-inch pipe is usually sufficient for a small stove.

Vacancies.

Aberystwyth Infirmary.—House Surgeon. Salary, £175. A knowledge of Welsh desirable. Applications before the 25th inst. (See Advt.)
Bristol General Hospital.—Physician's Assistant. Salary, £50, with board, &c. Applications to the Secretary by Feb. 15.
Castlebar Union, Castlebar Dispensary.—Medical Officer. Salary, £110, and £15 as Medical Officer of Health. Election, Feb. 25.
Drogheda Union, Monasterboice Dispensary.—Medical Officer. Salary, £110, and £20 as Medical Officer of Health. Election, Feb. 21.
Monaghan Union, Kilmore Dispensary.—Medical Officer. Salary, £110, and £15 as Medical Officer of Health. Election, Feb. 21.
Newcastle-on-Tyne Infirmary.—Senior House Surgeon. Salary, £100, with board. Applications to the Chairman of the House Committee before Feb. 22.
Radcliffe Infirmary, Oxford.—Junior Resident Medical Officer. Salary, £80, with board, &c. Applications, with testimonials, to the Secretary by Feb. 22. (See Advt.)

Births.

ANDERSON.—Feb. 8, at 14 Woodside Crescent, Glasgow, the wife of Professor McCall Anderson, M.D., of a son.
CANTON.—Feb. 9, at 17 Great Marlborough Street, London, W., the wife of F. Canton, M.R.C.S., L.R.C.P. Lond., of a son.
CORDNER.—Feb. 6, at Brookvale, Aghnacloy, the wife of Louis M. Cordner, L.K.Q.C.P.I., of a son.

Deaths.

BADDELEY.—Jan. 26, at Eastbourne, Paul Frederick Henry Baddeley, F.R.C.S., late Indian Horse Artillery, eldest son of the late Major John Baddeley, of the 7th Hussars, in his 75th year.
BODINGTON.—Feb. 5, at Sutton-Coldfield, Warwickshire, Dr. George Bodington, aged 82.
CLAPHAM.—Feb. 7, at Thorney, near Peterborough, John Clapham, M.R.C.S., aged 74.
COOPER.—Feb. 4, at Fillebrook Lodge, Leytonstone, William Cooper, M.D., aged 72.
DUPLEX.—Feb. 7, at 60 Torrington Square, London, George Duplex, M.D., aged 75.
FLETCHER.—Feb. 4, at Hope House, Kersal, Manchester, John Shepherd Fletcher, M.D., in his 60th year.
GADSBY.—Feb. 9, at his residence, Mansfield, Notts, of diphtheria, J. Topham Gadsby, M.D. Lond., aged 28.
HEY.—Jan. 31, at St. Andrew's Vicarage, Derby, after a short illness, Edward Hey, L.R.C.P. Ed., M.R.C.S., second son of the Rev. Frebendary Hey, of Belper.
JENKS.—Feb. 7, at his residence, 18 Circus, Bath, George S. Jenks, M.D., F.R.C.P., in his 83rd year.
JOFF.—Feb. 8, at Royal Terrace, Edinburgh, Surgeon-Major Jas. Joff, M.D., Deputy Inspector-General of Hospitals.
MOFFITT.—Feb. 8, at 20 Carlton Crescent, Southampton, Surgeon-Major Andrew Moffitt, M.D., A.M.D.
PALMER.—Feb. 6, at Kenilworth House, Southsea, the residence of his uncle, Edward T. Palmer, M.R.C.S., aged 23.

HEADACHES IN CHILDREN. (a)

By W. H. DAY, M.D.,

Physician to the Samaritan Hospital for Women and Children.

(C. included from page 135.)

DR. CLIFFORD ALLBUTT asserts, and I have heard it stated before, that "the headaches of students are often due to cerebral overstrain, but generally to optical effects in the eye, which are often wholly latent." (b) Now the first part of this statement is incontrovertible, students out of number with a sensitive brain cannot endure many hours of concentrated study without getting headache, and as long as it is continued, no remedy but rest of brain will bring any relief. As regards the latter part of the question I do not feel quite so sure of the connection between headaches and changes in the retina and optic nerve. Thus, "three cases of simple atrophy of the optic nerves occurring in members of the same family" have been recorded by Mr. Higgens. The respective ages of the children were fifteen, thirteen, and ten years of age. After the birth of the eldest of the three, the mother showed signs of syphilis. In two of the cases, the optic discs were of a dead white, but none of the patients complained of headache. The loss of sight being the only symptom. (c) It is, however, undoubtedly true, that long study will sometimes produce headaches of the nervous or neuralgic type from overstrain of the eye alone, and that properly adapted spectacles have remedied the evil, and enabled the sufferer to bear the strain of reading without bad effects. Inflammation of the discs due to this strain of accommodation may produce optic neuritis, and in the case of young subjects, it seems not unlikely that the inflammation may extend to the membranes of the brain itself. (d) Mr. Power has on a few occasions examined

for me the eyes of patients suffering from headache in which the sight has been weakened without detecting any optic neuritis or other important changes.

I will now say a few words on *toxæmic headache*. In fevers we have an instance of this kind of headache where the constitution of the blood is changed. As a consequence, a morbid sensibility of the nerve centres is induced, and the vessels and membranes of the brain become congested. When absorption of the fever poison takes place, every organ and every tissue through which the blood passes becomes impaired by it, and hence headache is a common symptom in simple fever, and is rarely absent in the acute forms. In young and strong children, the pain is often intense, the countenance is flushed, and the conjunctival vessels are injected. It may be associated with great restlessness, and even lead to furious delirium and coma. This is the form of headache met with in whooping-cough, measles, scarlet fever, and the poison of malaria. The treatment must of course be determined by the respective lesions, but cold applications, shaving the head, and the application of the ice-cap are often needed to relieve the suffering. As illustrating some of these remarks I would say in passing that, eighteen years ago, I saw a boy, æt. 10, suffering from measles, and when the eruption was fully out, he was attacked with most violent headache, chiefly across the forehead, the cerebral vessels were full, the face was flushed, and though quite intelligent at first, he wandered and was very delirious during the night. Cold applications to the head, a calomel and saline purgative soon relieved the symptoms.

I would briefly refer in this place to that form of headache (*uræmic headache*) occurring in connection with diseases of the kidneys from scarlet fever, when they cannot separate from the blood the excrementitious matters which have accumulated in it. These organs act pretty well for a time, but at length the morbid matters in the blood cease to exert a diuretic influence, and degeneration in their structure takes place. One of the most striking cases I have ever seen was that of a little girl, æt. 10, who came under my care in 1875 with acute desquamative nephritis and anasarca. The headache was entirely frontal, and continued for days together. When

(a) Read before the Harveian Society, February 2, 1882.

(b) The *Lancet*, October 29, 1881.

(c) The *Lancet*, November 19, 1881, p. 869.

(d) *British Medical Journal*, January 7, 1882, p. 1.

the local congestion had subsided, and the renal secretion had increased in quantity, relief was obtained, but if any animal food was taken, even in the shape of beef tea, the severe headache returned, and blood appeared in the urine. In such cases as these, it is most important to restrict the patient to a milk diet, and to withhold all animal food and stimulants, lest the congestion of the kidneys be increased.

One more point on this subject is not devoid of interest, the effect which toxic agents have on the blood and nervous system, when the atmosphere is vitiated by crowded assemblies in the imperfect ventilation of apartments. The accumulation of carbonic acid and expired air in school and lecture rooms is to be reckoned among the chief exciting causes of headache in young persons. I have seen many instances of children who have suffered from severe frontal headache through having to study in school-rooms where the amount of carbonic acid has been too great. The normal amount of carbonic acid in the atmosphere should be 4 volumes in a 1,000, but when it reaches from 50 to 100 per 1,000 volumes, fatal results are produced. Even when the percentage is reduced to 15 or 20 per 1,000 volumes, severe headache frequently results. The air of respiration in school-rooms is often times impure, as any person entering such places from the outer atmosphere will often detect. If it is vitiated and overcharged with carbonic acid, headache, sickness, and loss of appetite ensue, the force and frequency of the heart's action are lessened, the whole capillary circulation becomes reduced, and the brain is exhausted from the diminished quantity of blood it receives.

Boys and girls who are subject to hysteria are liable to a form of headache we may appropriately term *hysterical*, and unless we are acquainted with it we may commit grave errors in treatment. I have seen a few instances of it in boys, and all recovered. These patients are excitable and emotional, they often come of nervous parents, and are allowed to have their own way in most things. The mental state is most strange during a paroxysm. The great peculiarity is the extreme excitability of the nervous system which is sensitive and mobile. Such patients like sympathy, and will give way on the slightest provocation to obtain it. Surrendering themselves to any slight pain, they can insensify it at will; they throw themselves into terrible contortions, alarming everybody about them, and scream out from pain in the head, till at last they fall into a heavy kind of stupor from which they cannot rouse themselves. I have known the symptoms mistaken for disease of the brain, epilepsy and so forth. A boy, set. 10, was brought to me in January, 1881, suffering, it was said from headache, which he had had for three years at intervals. He was nervous and timid, and inclined to be mischievous; he would not look you in the face, and kept moving about the room, picking up things and then putting them down again. He was said to be easily ruffled and put out if he was contradicted or opposed in anything. I ascertained that he was worst at home, and better at school. When the attack was on him it would sometimes last for days together, and he would lie about unable to do anything. He said the pain was all over the head, but chiefly on the top, and not across the forehead. The pulse was quiet and the general health good. I did not think the pain was so acute as represented, and hinted that moral treatment was essential, and that he would be better at school under proper discipline, than remaining at home with his mother. A week after his visit to me, his mother wrote to say that he had had two attacks of headache, one on the 17th, and the other on the 19th; he writhed and rolled himself about on the floor, dashing against furniture, to the alarm of friends and bystanders. The attack on the last occasion continued for three hours. A year later (January 1882) it was reported that he had had one or two mild attacks of headache during a term at school, but since he had been home for his holidays he had had two. When the fit is on him his hands and feet are very cold, the head is hot, the body burning. If spoken to sharply he cries, and bursts into tears on the

least provocation. He cannot sit in a room with a fire, nor can he bear heat at any time. He often wakes up in the morning and says he is "dizzy and giddy," the pain begins at the top of the head, and then spreads over the whole head, and over the right eye. If the pain increases in intensity, he feels that he cannot control himself, but if his mind can be diverted when the pain begins, it often passes off. On the last occasion he threw himself into the greatest excitement, twisting the sheet round him, and writhing and gasping for breath. A medical man who saw him in the seizure pronounced it hysteria.

I now come to say a word or two on *organic* headaches in children. These arise from the same causes as in adults. Morbid growths from the brain or membranes, usually induce severe pain in the head with symptoms which often indicate the situation of the mischief. But it is to be remembered that tumours of the brain may attain considerable size before they produce any disturbance in its functions. Post-mortem examination has occasionally revealed a tumour in the substance of the brain which has produced no symptoms during life, and this is especially the case where it has been imbedded in one or other hemisphere, and does not press on the membranes or sinuses. Tumours of the brain of tubercular origin are more common than the other varieties. They are prone to produce inflammation and effusion into the ventricles. The chief symptoms of headache due to organic change are severe and fixed pain in the head, oftentimes paroxysmal, lasting for a time and then passing off, vomiting, constipation, impairment of intellect, disturbance of vision, convulsive movements, paralysis or coma. When a tumour approaches the surface of the brain, convulsions are most common; when situated towards the base of the brain, it may involve special nerves and lead to blindness. When headache is long and continuous, and anything like epilepsy or a convulsion, or blindness ensues, then we may suspect the presence of a cerebral tumour. In connection with blindness as a symptom of cerebral tumour, Dr. Hughlings Jackson has shown that it arises from the optic disc becoming white and atrophied from increased optic neuritis. The disc becomes red and swollen, the edges indistinct, the veins tortuous, and the arteries not well made out. The disc eventually becomes white and atrophied. I have thought it well to briefly allude to these changes in the eye, although I do not profess to be able to detect them like those who are skilled and practised in the use of the ophthalmoscope. In connection with this subject I may call attention to a rare and interesting case of hydatid of the brain, recorded by Mr. Goodall, in a girl, 14 years of age, who had headache of two or three months duration. In other respects her health was good. On the morning of September 20th, 1881, she had a sudden attack of vomiting which recurred several times during the day; in the evening she became insensible, and the following morning expired. After death there was found in the left centrum ovale majus on a level with the corpus callosum, a white opaque oval body, two inches in length, and $\frac{3}{4}$ of an inch in breadth. It contained fluid. At its anterior extremity was another cyst which had ruptured into the anterior lobe. No cysts were found in any other organ of the body. Dr. Beale regarded them as hydatid in origin. (a)

I hope the few and scattered hints I have thrown out have been enough to invite attention to a common yet, by no means, an unimportant ailment. On all sides it must be admitted that the subject possesses an interest which demands close attention to enable us to arrive at a right conclusion, and to determine the nature of our treatment. On a correct diagnosis, success or failure depends. I have not entered fully into the question of treatment, because this necessarily depends on the nature of the disturbance, whether sympathetic, congestive, irritative, toxæmic, organic and so forth. These are our great landmarks, always to be borne in mind if we would arrive at anything like scientific precision, and the best method of treatment.

ON THE RADICAL CURE OF INGUINAL HERNIA. (a)

By WILLIAM THORNLEY STOKER, F.R.C.S.I.

Surgeon to the Richmond Hospital, Dublin; Professor of Anatomy, Royal College of Surgeons, Ireland.

I WISH to lay before the members of the Surgical Society memoranda of two cases in which I have successfully operated for the radical cure of inguinal hernia, and which, I may say, are the only opportunities I have had of attempting this procedure. I do so in order that I may, if possible, provoke some discussion on the subject, and elicit the opinions of such members of the Society as have given the operation any consideration, or have had occasion to employ it.

It seems a somewhat remarkable fact that the operation, so far as I know, has seldom been performed in Dublin, and I desire by giving my own experience of it, to find out, why, in the hands of other Dublin surgeons, it has fallen into desuetude, and if possible, to stimulate its employment.

I am inclined to think that the infrequency of the attempt to effect a radical cure in this city is rather due to the easy-going, careless, and happy-go-lucky character of our people, than to any want of enterprise on the part of our surgeons. It is a factor in the Irish character which any one with much experience of the lower classes will admit, that the people seldom seek, or even permit any operation, until death or disablement stares them in the face. Witness the horrible cases of cancer and joint disease we so often see, where the unfortunate sufferers have avoided the hospitals and refused the knife, until their tardy submission to the inevitable comes too late.

Be this as it may, I speak with a large experience of the particular class of cases in question, for our truss department at the Richmond Hospital brings an immense number of ruptured persons to our doors, and when I have only had two cases in seven years submitting to operation, it seems to me to point clearly to the conclusion that our poorer countrymen will only submit to operations of necessity, while they refuse those of election.

It is interesting in an historical point of view to recall briefly the various operations which have, at different times, been proposed and practised for the cure of inguinal rupture, even although the conclusion we emphasise is, that with the exception of certain very recent measures, we must condemn them all.

The different modes of treatment which have at various times been employed have been conveniently classified by Mr. Spanton, to whose operation I will presently refer, under four heads.

- 1st. Operations designed to cause contraction of the sac.
- 2nd. Those designed to obliterate it by adhesion of its walls.
- 3rd. Those attempting a cure by plugging the inguinal canal.
- 4th. Those which in addition to this last, seek to draw the walls of the canal together.

1. Those cases where the contraction or removal of the sac has been attempted by the use of caustics, the ligature, or the knife. No higher science guided the application of these means than the desire to tighten up or remove as much of the sac as presented external to the abdominal wall, so that at best the result was the conversion of a complete rupture into a bubonocoele, and this at a risk the magnitude of which may be conceived when the barbarous methods are reflected upon, means so rude that they prevent any surprise at the usual mortality of two or three in ten which attended their use. Of caustics both the actual and potential were employed by the older surgeons; the former being used to such a degree as to penetrate deeply

into the tissues, while the favourite potential caustic was strong sulphuric acid, used so sharply as to cause destruction of the skin in the hope of inducing subsequent contraction. Excision of the sac, and of the testicle, and of the spermatic cord, the contents of which having been previously reduced, was practised by Celsus; while Paulus Egineta and Galen applied a ligature round the sac and cord, and either allowed it and the testicle to slough off, or removed them with the knife or actual cautery below the point of ligature. Another treatment anciently employed was that called the royal stitch, in which the sac was laid open and its edges brought together as high up as possible, so as to obliterate its cavity, this operation being in principle somewhat similar to that devised by Berault, and described by Ambrose Paré under the name of the *punctum aureum*, in which a piece of gold wire was placed around the exposed upper portion of the sac and cord, and twisted with enough tightness to ensure closure of the neck of the former. These latter methods had at least the advantage of conserving the testicle, an organ to which some importance is usually attached.

The operation of Langenbeck, which consisted in exposing the neck of the hernial sac at the external abdominal ring, separating it from the cord, and ligaturing it, was an improvement on the older methods, but like them, was, independent of its frequent fatality, open to the objection that, if successful, it was only so to the extent of converting a complete rupture into a bubonocoele; Langenbeck's own theory, that if the external part of the hernia was cured the canal itself subsequently contracted, being entirely disproved by the results obtained.

The second class of operations embraces all attempts to obliterate the sac by causing adhesion of its walls. It has been sought to effect this by passing setons through the sac, by injecting it with iodine or other substances, or by applying a truss with a hard wooden pad. The last of these methods was proposed by Richter, and has found an able advocate in the late Mr. L'Estrange, of this city; it has occasionally been found successful in the treatment of herniæ in adults, and is frequently so in those of infants. The difficulty in employing it in the adult is to produce sufficient pressure on the canal without injuring the spermatic cord. If it effects a cure at all, it is likely to do so thoroughly by producing closure of the canal, while the methods of treatment by the seton or by the injection of an irritant are not now employed, as they cannot effect more than the conversion of a complete rupture into a partial one, and this at a great risk.

There can be no doubt that a fair trial ought to be given in the cases of infants and young children to the curative effects of a well-applied truss before seeking relief by operation.

To the third class belong a number of operations, the best and most recognised of which are those of Gerdy and Wurtzer. By any of these methods it is sought to close the inguinal canal by invaginating the skin and areolar tissue of the scrotum into it, and retaining it there so as to form a plug. In Gerdy's operation the skin is retained in the invaginated position by means of a ligature passing through the anterior wall of the canal to the groin, the tube of invaginated skin being afterwards treated with caustic ammonia, so as to procure, if possible, the adhesion of its surfaces, and the complete obliteration of its canal. In Wurtzer's operation the retention of the invagination is effected by a needle which penetrates the canal in a similar direction to the ligature in Gerdy's, and which projects from a boxwood plug, which is left in the canal for some time for the purpose of producing adhesion of the invaginated tissue to its walls by dilating pressure.

The operations of Gerdy and Wurtzer are open to objections which have been so well expressed by Mr. Wood, that I cannot better explain them than in his own words:—"The invagination of the hernial sac from the scrotum into the inguinal canal leaves, by its reduplication, a circular fold, or *cul-de-sac*, which, from its closer attachment to the spermatic cord and posterior structures, extends much lower down behind than in front. In

(a) Read before the Surgical Society of Ireland. The discussion will be found on page 165.

Gerdy's operation, and in those following the principle of his plan, no attempt whatever is made to close this posterior fold. Adhesion is simply sought and obtained at the anterior part of the inguinal canal, at the apex of the invagination, or is futilely attempted on the inner surface of the invaginated cord. In Wurtzer's method, the theory is—that the circular dilating pressure of the plug suffices to cause adhesion of the serous surfaces round the entire circumference of the neck of the sac, as well as consolidation of the hernial canal." In which conclusion I quite agree, and for the reason set forth, that no amount of pressure which could be borne by the patient would suffice to produce adhesion of the compressed serous structures, guarded from pressure as they naturally are by layers of areolar tissue, fascia, and aponeurosis. Into this posterior *cul-de-sac* of inadherent peritoneum some of the abdominal contents will eventually find their way and reproduce the original deformity, a consummation to which the bulk of the invaginated skin and the difficulty of obliterating its free surface must lend itself.

The fourth class of operations is that which not only invaginates certain tissues so as to plug the canal, but in addition, draws its walls together, so as to effect its closure more completely. The only operations of this class which have until lately been much practised, are those of Wood, who may claim to have been the first surgeon who proposed and carried out a radical treatment based on sound reasoning, and a truthful comprehension of the surgical anatomy of the parts.

It may fairly be asserted for Mr. Wood, that his operation fulfils every requisite indication for a cure, by affording a substance to invaginate, by retaining it in its position in the canal, by drawing the walls of the canal together so as to close it, by engaging the posterior or movable boundary of the inguinal passage, as well as its more fixed anterior one, and by exciting enough inflammation to ensure a copious lymph exudation and a subsequent cementing of the parts together, consequent upon the organisation and contraction of that lymph. It offers for invagination a material less bulky than the skin which was formerly employed, and more likely to become completely incorporated with the walls of the canal, more likely therefore to draw them together, and certain to become completely obliterated on its tubular or cutaneous aspect—an obliteration not easily obtained when the skin itself was pushed into the inguinal canal. It also affords a certain and safe drain for serum or pus, the wire acting as a conductor, and so affords the greatest immunity from the burrowing of matter towards the peritoneum or between the abdominal muscles.

In fine, surgeons may differ as to the propriety of attempting a radical cure, or as to the particular operation they may select, but there can be no dispute about one point, that all operations in use previous to the publication of Mr. Wood's most admirable monograph in 1863, were either extremely dangerous—or even barbarous—or that they failed to effect a complete or permanent cure in the vast majority of cases.

Since Mr. Wood's operation came into notice, it seems to me that but one other procedure can claim to be discussed with it, I mean that of Mr. Spanton, advocated in the *British Medical Journal* of December 11th, 1880, to which I will refer later on.

It is unnecessary for me to give any detailed description of the Wood's radical operation to an audience like this; suffice it to say, that of the three forms of procedure originally described, namely, the operation by pins, that by the thread and compress, and that by the wire, I used the latter. The first of these, where pins are used, is seldom applicable in cases of small inguinal or congenital ruptures occurring in children, and that by the thread, Mr. Wood tells me, he has latterly abandoned, as he finds the wire excites less suppuration, and is less likely to be followed by burrowing of matter, because the track of the wound is kept straight, and the serum escapes freely along the wire.

In both of the following cases the same operation was performed—namely, the ordinary subcutaneous wire operation of Wood, three passes of the needle being made, and the third pass including the attachment to the internal pillar of the ring as well as the hernial sac. Mr. Wood seems to place increased importance on this last, and there is no doubt that even in small cases it is advisable to have the additional security which it offers, both by securing the lower boundaries of the canal and by giving a better hold on the sac.

Case I.—Thomas Finn, a healthy, muscular labourer, æt. 23, was admitted into the Richmond Hospital on August 28th, 1874. He had a small, complete, oblique, reducible, right inguinal rupture, which he had first noticed a few weeks before, and for the relief of which he sought admission. He was a timid, nervous person, and I believe the reason why he desired a cure to be attempted—contrary to the usual apathy displayed in such matters by the poorer classes in this country—was an absurd terror, which no argument could move from his mind, that the rupture would interfere with his generative powers.

I operated on September 16th, chloroform being used. He suffered some pain along the iliac crest, and in the testicle, for two or three days; it was easily allayed by small doses of comp. soap pill at night. He required a purgative on the fifth day, the bowels not having acted, and half an ounce of castor oil was administered with good effect. The wire was untwisted on the 10th day, and removed on the 14th. The wound healed completely in 12 days afterwards. He was kept in bed until Oct. 12, that is 26 days from the time of operation. When the wire was removed a compress of lint and a spica bandage was applied and worn until a fortnight after he had left his bed, when, the tissues being sufficiently indurated to bear the pressure, a light truss was applied, which he wore during the day, until he left the hospital. For purpose of observation, I retained him in hospital for two months after he had commenced to wear the truss, during which time he did light work about the ward, and when he left to return to the country place from which he came, the inguinal canal remained consolidated, and the cure to all appearance promised permanency.

Case II.—Joseph Carpenter, æt. 22, a butcher by occupation, tall, muscular, of slender build, who suffered from a reducible, oblique, scrotal rupture of considerable size, on the right side, was admitted into the Richmond Hospital during the past summer. He desired to have a radical operation performed, as he hoped to qualify himself for the constabulary. I operated on August 31st, ether being the anæsthetic used. On the fourth and seventh days half-ounce doses of castor oil were necessary, the bowels afterwards acting naturally. He suffered no pain and required no anodyne medicine. The wires were untwisted on the 9th day, and removed on the 16th, two intermediate attempts to remove them being unsuccessful, partly because they were entangled with the fibrous structures, and partly because the patient was very intolerant of any pain. Eventually they were removed under ether; he refused to submit without an anæsthetic to the attempt to withdraw them; 8 or 10 days afterwards the wound healed completely. Subsequent to the removal of the wires, a spica bandage was worn, and continued for some weeks, when a light truss was fitted to him, and he left the hospital ten weeks after the operation with the canal in a perfect state of consolidation and closure.

In the first case the operation was done without anti-septic measures, in the second they were rigidly observed. In both cases the wires were withdrawn in a direction upwards and outwards. The diet was low only for three or four days following the operation, after which it was normal, as it is essential to good reparation to have good nutrition.

In both cases there was some slight swelling of the testis for a few days after the operation, owing to the constriction of the cord. This passed off without giving any

trouble, and I may mention that it is one of the points which Wood considers desirable, as showing proper closure of the canal. No ill effects to the testis have been observed to follow the operation. Mr. Wood follows the antiseptic plan rigidly, as he considers "an aseptic result desirable in all cases. If the wires are properly applied, adhesion must take place in their track, and suppurative action is not likely to make that adhesion more effectual."

I think the use of the truss after operation is capable of causing harm instead of good. It must be remembered that a very strong truss or one with a very convex pad, may possibly press its way into the lower part of the inguinal canal, and so tend to separate the newly adherent structures and assist in reproducing the rupture. I have therefore been careful to employ a very light truss, with a flat pad, to direct the patient only to wear it when engaged in walking or making any exertion, and to discontinue it after some months.

The operation devised by Mr. Spanton is performed with an instrument which I am able to exhibit to the Society, owing to the kindness of Mr. Thomson, who has lent it to me. It is something like a corkscrew, but with a flat point, so as to pass through the fibrous structures without doing much violence to them; it is broader near the point than at the handle, so that as it is screwed onward into the boundaries of the canal, it approximates them to each other. The same preparation of the patient is made as for Wood's operation, by shaving the skin, incising it, and separating it from the subcutaneous tissue to such an extent as may be necessary to permit the invagination of the latter. The rupture being reduced, the invagination is effected by the index finger of the left hand, when the screw, held in the right hand, is made to pierce the skin of the groin, and the aponeurosis of the ext. oblique muscle at a point above the outer border of the conjoined tendon, through which it is then passed, by giving it a half-turn. It is then twisted towards its axis, being directed downwards and inwards in such a way that as its point crosses and recrosses the canal it passes first outwards through the invaginated sac and the external pillar, then inwards so as to catch the internal pillar of the ring, and finally outwards again so as to pass through the scrotal wound in the skin. The part is then dressed and bandaged antiseptically. The instrument is usually removed in about a week, and the wound allowed to heal.

The advantages claimed for this operation by its author are: that instead of only catching the boundaries of the canal at two or three points, as in Wood's operation, it seizes them at a greater number, and owing to this, to the numerous points at which the sac is transfixed, and to the compelling action of the screw in drawing the parts together, it effects a more complete closure of the canal. The plug, too, is described as more cylindrical in form, less conical, and therefore less likely to slip downwards from its position. As in Wood's operation, the finger which performs the invagination is used to direct the point of the screw through the proper tissues, and to protect the cord and deep epigastric artery from injury.

This operation, so far as it has been tried, appears to have afforded most favourable results, both as regards the proportion of cures and its immunity from danger. It remains yet to be seen how it will compare with the method of Wood, and whether its results will prove equally permanent, and its immediate performance as free from danger. As far as I can see, the results might be expected to be as good, if the screw can be applied so as to transfix the sac and the boundaries of the canal in the way described, while it seems to offer little risk in the hands of careless or inexperienced operators, and to be free from the difficulty of withdrawing the wires, which may occur in Wood's method. On the other hand, it is but fair to say that Mr. Wood claims that with due precaution and enough skill, such difficulty of withdrawal never occurs, and beyond this, I for my own part feel that Wood's method offers to a person well acquainted with the

anatomy of the parts and possessing sufficient dexterity, a certainty as to what he is securing, and a power as to what he will secure, which the more easy operation of Spanton cannot offer. For ease I would select the screw operation, for certainty, that of the wire. Mr. Wood tells me that if, when the wire is untwisted, you seize each end with a pair of pliers and pull stoutly, you can remove the kinks without injury to the parts, and easily extract the wire. I tried this plan in my last case, but nevertheless I experienced a good deal of difficulty, and I apprehend that it is only experience of the operation that will enable a surgeon thoroughly to overcome this trouble. It is a matter of much importance to do so, because of the obvious danger to new adhesions, to say nothing of other structures, that may result from a very forcible effort.

I am strongly of opinion that the mere drawing together of the walls of the canal at the time of operation in Wood's method is a matter of minor importance, and that it is the abundant exudation of lymph and its subsequent organisation and contraction, together with a due invagination of areolar tissue to act as a sort of *point d'appui* for such contraction, that offers the chief element of success. I do not, therefore, believe any very tight twisting is necessary, but I hold that in order to have the lymph exudation as diffused and extensive as possible, as though a seizure of the boundaries of the canal is necessary as if the *immediate* drawing of them together was essential. I can offer no better evidence in favour of Wood's operation than by quoting parts of a letter I have received from him, which states his results up to the present time. He says:—

"The proportion of cures out of upwards of 300 cases of operation has been 75 to 80 per cent., in favourable cases, and from 50 to 60 in large and severe cases. In many I have examined after 20, 14, 10, and 5 years' interval, the cures have remained perfect, no truss having been worn after the first year after operation. Last week a case of mine was shown at the Fellows' examination at the College of Surgeons, 14 years after operation. The week before I showed a case at King's College Hospital, 20 years after; and on Saturday last I showed at the same place a case 4 years after. This was a very large case, which had been operated on in India previously unsuccessfully. I have seen a great many between 2 and 3 years after, and the results have shown the proportion I have mentioned.

"In no case have serious symptoms of peritonitis occurred, and I have had no death in the last 200 cases of the subcutaneous wire operation. In twenty cases I have operated under spray, taking away sac and omentum in large irreducible herniæ. One of these I lost in the very severe cold of the great snow-storm of last winter from bronchitis, with clot in the heart. No serious peritoneal inflammation was found in that case."

These results speak more eloquently than I can of the advantage and safety of the operation, and are most convincing, because they show that the cases in question have not been dubbed as radical cures until enough time had passed to demonstrate their stability. The remarkable freedom from peritonitis is worthy of attention, as showing that one danger which might be apprehended is more imaginary than real. It is, I think, easily accounted for by the callous condition which the peritoneum soon assumes in the case of a hernia and in the vicinity of its neck.

Of course, there can be no doubt, that since the introduction of antiseptic surgery, the procedure of exposing and isolating the neck of the sac, tying it, dividing it, and then stitching the pillars of the canal together, has obtained a relative degree of safety as compared with its use previously, which has given it a recognised place among the operations for the cure of rupture practised at the present day. Such a proceeding was, previously to the development of antiseptic surgery, only attempted by modern surgeons in those cases where, having been compelled to operate for strangulation, the opportunity was seized to add to the *necessary* operation, by attempting a

radical closure of the hernial opening, Mr. Wood himself having urged the propriety of completing an operation commenced for the relief of strangulation by an effort to effect a radical cure.

Max Schede, of Berlin, published in 1877 a series of eight successful cases, some inguinal, and some femoral, in some of which the operation was undertaken because of strangulation, and in others was an operation of election, and in all of which, following Lister's method, he laid bare the neck of the sac, tied it, removed it below the ligature, and stitched the pillars together. Sir William MacCormac has also performed the operation, and Professor Socin, of Basel, has followed a similar plan in seventeen cases, which all resulted in success: ten were inguinal, seven crural, all the crural and three of the inguinal being previously in a state of strangulation. No doubt these results are good, but it requires a more extended experience and a longer observation to show a safety and a permanence of result equal to Wood's great series of cases; and while such observation is being made, I can say for myself that I will remain loyal to Wood's operation until the more daring but easier plan I have mentioned last has demonstrated its claim to adoption.

UNINTOXICATING WINES. (a)

By NORMAN KERR, M.D., F.L.S.

THE ripe fruit of the vine possesses cooling, refrigerant, blood-depurant properties. The unfermented juice of the grape is rich in sugar, contains other nutritive constituents, and acts as a gentle diuretic and aperient. So excellent a therapeutic agent is the ripe grape, that in Switzerland and other continental regions the grape (*cure de raisins* of France) has achieved an acknowledged reputation. From early times to the days of Cullen and Pereira, the virtues of the grape have been highly extolled by the medical faculty.

In fermented intoxicating wines the most valuable properties of the grape are either absent altogether, or present in greatly diminished quantity, alcohol and other new products being formed at the expense of the saccharine, albuminous, and other useful components of the unfermented juice.

Alcohol is an irritant narcotic poison, and is contra-indicated in many inflammatory conditions, where the cooling, refreshing, purifying, and nutritious qualities of the unfermented grape-juice are markedly beneficial. Hence we find that, in addition to the fresh grapes, dried grapes, or raisins, and the unfermented juice, have been a favourite prescription in ancient as well as modern times. Dodoens ("Herbal," p. 651, Lond., 1578) speaks of the "dried raysens" as "good for cough and all diseases of the lungs, kidney, and bladder." Louis Cornaro had his strength renewed at the beginning of every vintage by new wine. Cæsar Frederick in the sixteenth century (Kerr's Collec. vii., 142; Hakluyt II., 339-375) relates how a friend of his was ordered in Cochin to drink new unfermented wine night and morning.

Dr. Russell, in his "Natural History of Aleppo," says that the juice of ripe grapes inspissated was largely used in the treatment of febrile inflammatory diseases.

For the last twenty-one years I have been in the habit of prescribing the unfermented wine manufactured by Mr. Frank Wright, Chemist, 68 High Street, Kensington. This, which is a natural, red, unfermented wine, prepared from grapes imported from the Continent, I have found of considerable value, taken either alone, with iced or aerated water, in fever or in phthisis, with hæmoptysis. In hæmorrhages generally, when alcohol is contra-indicated, this wine is especially useful. In one severe case of small-pox, where recovery was despaired of, the patient, a woman, aged twenty-eight, could swallow

nothing for nearly eight days but this unfermented wine-and-water in the proportion of half and half.

But the taste of invalids, as of the healthy, is capricious, and I have long endeavoured to persuade some enterprising Englishman to supply a variety of unfermented wines as articles of medicine and of diet. At length Mr. Wright has, at my suggestion, imported from abroad several unfermented wines, which he now offers along with the wine he has himself been manufacturing for the past quarter of a century.

These newly-offered wines are—

RIESSLING (German).—A pale yellow, thin, delicate bouquetted wine; dry (a), with slightly acid taste.

MUSCAT (French); from the "Muscat" grape of the Pyrenées Orientales).—A pale pink, full-bodied, very sweet, luscious wine, with the distinctive flavour and bouquet of the Muscat grape, well marked.

LACHRYME CHRISTI (Italian; from the celebrated grape of that name grown at the base of Mount Vesuvius).—A thin, fine wine, with a characteristic flavour which is both nutty and fruity, and a sweet sub-acid taste.

ALTO DOURO (from the grape which yields the best genuine fermented port wine).—A fine, sweet wine, with a delicate nutty flavour, and of a light-red colour.

BORDEAUX (Bordeaux).—A dark red-coloured wine with considerable body. Has a fruity aroma, and is pleasantly acid to the taste.

MADEIRA (Madeira).—A rich red-coloured wine, with medium body, and a delicate, peculiar, but agreeable flavour.

CONGRESS (American; when fermented has a large trans-Atlantic sale as "American port").—Is a deep purple, very dry wine, with tolerable body, and with a rough, astringent, fruity flavour.

These wines have considerable dietetic and hygienic merit. While valuable medicinal remedies, they are wholesome and acceptable social beverages, when taken moderately by those with whom they agree. With eight varieties of genuine, pure, unfermented wine, there should be little difficulty in suiting almost any palate. It seems to me a favourable omen for the future sobriety of our country, that the wine cellar can now be stocked with a varied assortment of good, sound, unfermented wines.

Clinical Records.

EAST LONDON CHILDREN'S HOSPITAL.

A Case of Typhoid Fever, with Fall of Temperature on the Ninth Day.

Under the care of Dr. EUSTACE SMITH.

(Reported by Mr. SIDNEY DAVIES, B.A., M.R.C.S., Clinical Assistant).

C. M., æt. 9, was admitted into the hospital on September 23, 1881. Her father's family was phthisical, and a brother had died of some disease of the brain at the age of eighteen months.

The patient had been born a healthy child; had cut her teeth and walked at the usual time, and had had no previous illness, except whooping-cough at the age of four. Her present illness began on September 15, when she complained of being cold, and had a frontal headache. She was quite well the day before. Accompanying the headache she had abdominal pain, and was said to have been burning hot at night. She lost her appetite, and became languid and inclined to lie down. The headache went away after lasting four days. Two doses of rhubarb were given by her friends, which caused looseness of the bowels, with light yellow

(a) "Dry" is not used here in the same sense as when describing intoxicating wines. Dry fermented wines are generally understood to be wines from which the sugar has more or less disappeared by fermentation. The dryness I have remarked in some unfermented wines has reference only to the taste, and arises, probably, from the combination of tannin with acid in the original juice.

(a) Read at the Quarterly Meeting of the British Medical Temperance Association, on February 14th, 1882.

motions. On the 21st she had some castor oil, which caused two actions of the bowels.

At the time of her admission the child was said still to have abdominal pain, coming and going. She felt better towards evening, and slept fairly well at night, but was more feverish then. The face frequently flushed and grew pale. She had had no sickness nor epistaxis. The diet, since the onset of the fever, had included meat-pie, jam, fish, &c.

The mother attributed the illness to sitting in the damp. There was no other case of illness in the house, but a drain near the house had been recently disinfected.

When first seen, on the 22nd, the temperature was 102°, and there were rose spots on the abdomen.

When admitted on the 23rd there were no spots to be seen. The abdomen was not much distended. Tongue slightly furred. The spleen could be felt two fingers' breadths below the ribs. Temp. 102·6 in the evening.

Sept. 24th.—Temp. 97°, pulse 80. The child is knitting in bed, and says she feels better. Abdomen is a little more distended and tender about the umbilicus and right iliac fossa.

25th.—Patient says she feels no pain. She is sweating a little about the face. No tenderness in iliac fossae. Some gurgling in right iliac fossa. Tongue cleaner. Bowels not open since admission. Highest temp. during the day, 99·2°.

26th.—A formed motion of a slaty colour was passed to-day. Highest temp. 99·8°.

27th.—The spleen is first felt below the ribs. There are no rales about the back of the chest. Highest temp. 100·3°. It varies about 2·5 in the twenty-four hours.

30th.—Spleen normal. A light-coloured, very offensive motion passed, consisting of small faecal masses. Temp. subnormal the last two days.

Oct. 4th.—The temp., with one exception, when it rose to 99·5°, has been subnormal for six days. Patient ordered solid food. Has passed no motion for three days.

5th.—Patient had some bread, gravy, and potatoes. Is looking well and in good spirits. Temp. rose to 99·3°.

6th.—Temp. rose to 100°. One motion.

7th.—To-day had soup and suet pudding. Temp. rose to 102°. One motion, which was not seen. Ordered milk diet.

8th.—Temp. 102·2°, pulse 134, resp. 36. No cough. One typical typhoid spot seen near umbilicus. Tongue furred in the centre, and red at the top and edges. Edge of spleen just felt below the ribs. No abdominal pain or distension. Temp. has varied from 96·6° to 103° in the twenty-four hours.

11th.—Temp. continues to vary about 4° in the day. Abdomen distended. Spleen two fingers' breadth below the ribs. A few typhoid spots seen on the back, and one on the abdomen. Tongue rather dry. Bowels constipated.

13th.—One normal motion.

15th.—Temp. varied from 98·6° to 101°. Child looks cheerful. Spleen one finger's breadth below ribs. Abdomen still swollen; abdominal wall flaccid. One or two spots seen.

19th.—Temp. from 97·4° to 99·4°. Child looks comfortable. Bowels open six times in the twenty-four hours. The motions resembled pea-soup, with a greenish tinge, and contained some clots of varying size, one as big as a broad bean; also some shreddy matter. Tongue rather dry. Some fresh spots on the abdomen. Spleen one finger's breadth below the ribs. No abdominal tenderness. Heart healthy; sounds rather soft. Temp. below 99·5° for last three days.

26th.—Temp. from 98° to 99°. Spleen two fingers' breadth below ribs. Abdomen still swollen. One fresh spot on epigastrium. Tongue furred and dry. One semi-solid motion; dark and offensive. No blood. Heart sounds very soft. Ordered brandy ʒj. every three hours.

Nov. 1st.—Temp. normal for two weeks. Abdomen still rather distended. One or two suspicious spots. Spleen one finger's breadth below ribs.

On Nov. 12th patient went to the St. Albans' Convalescent Home.

Remarks.—This case is very interesting, as showing that the temperature in typhoid fever may fall below normal on the ninth or tenth day, contrary to the generally received opinion. When the patient came in there was one doubtful spot, and the spleen was enlarged; but the early fall of the temperature seemed to exclude typhoid, and as she

seemed so well the patient was put on meat diet on October 4th. Immediately the temperature rose, the spleen enlarged, spots appeared, and the child passed through a well-marked relapse of typhoid fever.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

RESECTION OF THE SPINAL NERVE.—M. Tillaux occupied the whole meeting of the Académie de Médecine with a communication, which from its novelty and the interest attached to it, merits to be cited in full. A woman, *æt.* 35, entered in Nov., 1879, La Charité, presenting an affection not yet described. When her head was supported and maintained in a certain position she felt nothing abnormal, but immediately that the head was abandoned the patient felt it drawn in an irresistible manner in a position always the same. The chin turned to the left, and the head by this rotatory movement reclined on the right shoulder as in ordinary wry neck due to retraction of the sterno-mastoid muscle. However, there was no appreciable muscular contraction. The patient, who seemed utterly powerless to control this kind of spasm, experienced excessively acute pain in the left side of the neck and at a point corresponding to the first cervical vertebra. M. Denon, in whose service the patient was, considered the affection to be functional spasm of the muscles of the neck, and treated it for several months by the continued current, the application of the magnet, metalotherapy, &c., but without the slightest benefit, and the patient left the hospital a greater sufferer than when she entered. All work having become impossible, she applied in May, 1880, for admission to the Hôpital Beaujon, when she was placed under the care of M. Tillaux. Three weeks afterwards M. Tillaux, thinking that the sternal branch of the sterno-mastoid muscle was the cause of this curious kind of torticollis decided upon the resection of its tendon. The operation in itself was successful. The wound healed rapidly, but the situation of the patient remained exactly the same, and he requested that something more should be done. It was then M. Tillaux thought of resecting the spinal nerve. This nerve almost immediately on its exit from the posterior foramen divides into two branches, one inner anastomosis with the pneumogastric, and the other extern passing first close to the angle of the jaw and across the parotid gland reaches the middle of the sterno-mastoid muscle where it divides into two branches, one of which supplies the muscle above-named, while the other descends lower down to reach the trapezius where it loses itself. These two muscles are animated by this external branch of the spinal nerve, but not exclusively. These two muscles play the principal part in true torticollis, and one might naturally hope to arrest functional spasm by modifying their nerve supply. Already stretching had given good results to Moesig in an operation he had practised on a priest. But M. Tillaux, by an experiment in the dissecting room, found that when the spinal nerve was drawn upon the movement was communicated to the bulb. This fact made him prefer resection to stretching, as he was afraid of producing a lesion of the bulb. Accordingly, on the 15th Dec. an incision was made over the posterior border of the sterno-mastoid, and soon the spinal nerve was brought into view and seized with a blunt hook and resected for the distance of an inch. Immediate union of the wound with antiseptic dressing concluded the operation. As to the results, they are satisfactory. The patient is not completely cured, but she enjoys an evident control over the spasm. M. Tillaux thinks that at the end of a couple of months the affection will have altogether

disappeared. The question might be asked if the resection might not in some way affect phonation? Claude Bernard, it was true, had considered the spinal nerve in all its divisions as a nerve of phonation. According to him, the external branch on contracting the trapezius, and the sterno-mastoid contributed to complete and prolong the movements of the thorax during singing, but his patient has not given any evidence of the voice being modified.—M. Guérin observed that the case of M. Tillaux was remarkable in that resection and simple section of the ninth nerve was practised. The latter operation was done by him several times in similar cases which he considered should be classed under the title "spasmodic torticollis," which Amussat failed to distinguish from true torticollis produced by muscular retraction. For the class of torticollis by retraction the tendons of the affected muscles should be cut, whereas in spasmodic torticollis, on the contrary, M. Guérin operated by section upon the centre of the muscles themselves in order to modify their innervation. M. Tillaux has just shown that in cutting through the centre of the sterno-mastoid muscles, the spinal nerve was included in the section.—M. Tillaux replied that he was well acquainted with cases of spasmodic torticollis, but it did not seem to him that his case could be classified under that head, for where there is spasmodic action the movement is *brusque*, and the muscle feels hard to the touch. In this patient the operation of the rotatory movement was gradual, and the slightest obstacle arrested it, and palpation could not discover any contraction of the muscles. This discussion, in which other members took part, was concluded by M. Guérin, who confessed that he was inclined to admit that amongst the spasmodic wry necks the case of M. Tillaux formed a new kind; but where there is spasm there is always muscular contraction, and subcutaneous section of the muscle can always be tried, not only without danger, but with advantage.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 10TH.

The President, JOSEPH LISTER, F.R.S., in the Chair.

Mr. KNOWSLEY THORNTON brought forward

A CASE IN WHICH SUPPRESSION OF URINE WAS THREATENED SEVERAL TIMES AFTER OVIOTOMY.

On each occasion packing the arms in cold wet towels relieved the symptoms, and the patient made a good recovery, and has remained in perfect health since. The following is a brief outline of the case:—J. W., æt. 39, married, and the mother of two living children, the youngest, æt. 7½, was admitted into the Samaritan Hospital in October, 1880. *History.*—Never strong. During last seven years has had three stillborn children and two miscarriages. Since last miscarriage has had irregular and too frequent menstruation. Abdominal tumour first noticed early in last pregnancy, September, 1879. A few weeks before admission Dr. Pierce, of Denbigh, tapped the tumour, and removed twenty-four pints of greenish fluid. *Condition on Admission.*—Looks older than her age, and has a waxy skin. Kidneys act badly, and skin is dry and harsh. No albuminuria. Ovariectomy performed November 4, 1880, and tumour of right ovary removed, weighing, with contents, 28 lbs. Operation of average difficulty; a good deal of sponging necessary; occupied an hour. Temperature and pulse rose rather rapidly, and on the day after the operation the urine was scanty and dark, and the kidneys were very irritable. Digitalis and cit. of potash were given, and next day urine was free and loaded with lithates. On the fourth day the kidney irritability returned, and the temperature and pulse rose again. Sympathetic vomiting came on, and on the sixth day, the condi-

tion appearing critical, the arms were bared and packed in cold wet towels, which were kept wet with iced water. In twelve hours all bad symptoms had disappeared. The towels were allowed to dry, and in five hours the patient was as ill as ever. The towels were wetted again, and were kept on for forty-eight hours, during which time the patient appeared quite well, and the wound was dressed for the first time, and found soundly healed, and all the sutures were removed. The towels were removed, but during the day the kidney symptoms and sickness gradually returned, and they were re-applied. Temperature and pulse remained unaffected, but the kidney symptoms at once yielded. On the eleventh day they were again removed, and on the twelfth, the temperature being normal, the patient was allowed to get up. A few days later she went home, and Dr. Pierce writes that she is now in better health than she has enjoyed for some years. *Remarks.*—Mr. Doran has shown by his post-mortem observations that advanced granular disease of the kidneys is common with large abdominal tumours, and we know that this condition frequently exists without any clinical evidence of its presence. In the present case no albumen was detected, and though the kidneys acted badly before the operation, they were equal to the excretion of a fair quantity of urine, loaded with lithates, on the second day after operation. The symptoms detailed at length in the paper were clearly due to the kidney condition, and the application of cold wet pack to the arms on three separate occasions acted like a charm. To what is this rapid action to be ascribed? The author discusses the method of applying dry and wet cold, not only to reduce temperature, but to relieve serious internal congestions. In the latter class of cases he believes the action to be a reflex one through the nervous system, and not a mere cooling of the blood generally. He refers to the action of external chill in producing internal inflammations, and to the well-known action of counter-irritants. While believing that ordinary cases may be explained by one or other of the theories mentioned, he is still at a loss to explain the rapid action on the kidneys in this case from such a very restricted pack. The repetition of the treatment, and its unflinching effect on three separate occasions, and especially on the last, when the pulse and temperature remained unaffected, make it clearly a case of demonstrated therapeutic action; not a mere coincidence.

THE PRESIDENT observed that the case recorded possessed a considerable degree of interest in a therapeutical sense, since the frequency with which the effect commented on was produced as a consequence of the measures resorted to removed any doubt as to the relation of cause and effect. Mr. Thornton had afforded a possible explanation of the manner in which the wet sheet brought about the results accredited to it, in his description of the effects observed to follow the use of the ice-cap. It should be remembered, however, that the brain would not be cooled by the application of such a cap; the action set up would be of reflex character; the arteries of the brain contracting under the influence of cold, the flow of blood would undergo diminution, and thus a less amount of impure blood would find its way to the organ there to set up changes which would find expression in the condition of distant parts. Some years ago, said Mr. Lister, he had demonstrated that raising of the limbs not only brought about local depletion by emptying the veins, but also by means of arterial constriction which accompanied the act, and thus was afforded a means of explaining various effects produced on the circulation by changes in position, such effects being referable to sympathetic causes. He recollected having been consulted by a man who suffered severe pain in the testicle while standing, but which entirely ceased when the patient sat down and elevated his feet. The explanation of this was that the arteries of the testicles sympathetically contracted with those of the raised limb, and it could be taken also to demonstrate that an important influence might be brought to bear on the pelvic viscera in connection with variations in the position of the limbs. A familiar instance of this kind of sympathy between arteries of different parts was offered in the relief of epistaxis by raising the hands. In this case the arteries of the uplifted limb contracting, those of the Schneiderian mucous membrane likewise became altered in calibre, with the result that cessation of hæmorrhage followed. Professor Tait, whose accurate powers of observation might be implicitly relied on, had assured him (Mr. Lister) that when, while fishing, he waded much through the water, he invariably suffered from an attack of epistaxis,

which, however, he could at once relieve by raising his hands. The connection between the two conditions and their relation to the position of the limbs, however apparently overdrawn, was true, and might be rationally explained on the assumption of sympathetic action; and in the case of cold applications, a like sympathetic contraction of arteries distant from those originally affected might with equal certainty be assumed to occur.

Dr. WILLIAMS said he had made trial of the ice-cap in cases of pneumonia and tuberculosis, and found the effects produced depended on the nature of the cause to which high temperature was due, whether viz., it was consequent on a general blood vitiation or on textural changes in a limited region. In the latter class of case no good followed the use of the ice-cap in his experience.

Mr. THORNTON thought it would be desirable in any future similar case to make trial of treatment by raising the arms, as suggested in the valuable remarks of the President. Contrary to Dr. Williams' experience, he found the ice-cap most efficacious in treating local congestions. In general blood-poisoning he had found it valueless, except as a mere cooling agent locally.

Mr. BALMANNO SQUIRE read

NOTES OF A CASE OF ERYTHEMA IRIS

(exhibited at the last meeting). A woman, *æt.* 28, presenting a copiously sprinkled eruption limited to the palms of her hands and fingers, and the backs of the ends of her fingers. The eruption had lasted a month. Within the last two years she had had two previous attacks, each lasting three weeks. Each spot of the eruption consisted of a circumferential, definitely raised, faintly-pink ring, enclosing a disc-shaped, flat, unraised, dark-coloured, brown-crimson, abruptly limited stain, disappearing completely for the moment on pressure, the centre of the dark crimson stain being faded, and of a pale buff yellow hue. The average diameter of the spots, including ring, was eight millimetres. The eruption was attended with a sensation of itching, and occasionally of burning. There was also considerable tenderness of the affected skin, so as to preclude any use of the hands. There was no desquamation, nor was there any vesication, but, by the patient's account, the previous attacks had terminated in free desquamation.

Dr. FINLAY showed

A CASE OF ANEURISM OF THE ASCENDING AORTA IN A WOMAN, *ÆT.* 32.

She complained only of shortness of breath on exertion, and a slight cough at times. She had no difficulty in swallowing, and the pupils were equal. An oval-shaped pulsating swelling, 3 inches by 2½, and projecting about half-an-inch from the surface of the chest, appeared to the right of the sternum, and extended in an almost vertical direction from the lower border of the second to the lower border of the fourth costal cartilage. There was no discolouration of the skin, nor enlargement of cutaneous veins. Over the swelling there was a thrill and a loud double murmur, the diastolic part being loudest and longest. A double murmur was also heard at the heart's apex, which appeared in the fifth interspace in the nipple line. The murmurs were heard generally all over the chest, both back and front. They were also heard in both carotids, and there was visible pulsation of the vessels of the neck. Dull percussion was found over the tumour, shaded off for some distance beyond. Inspiration was wavy at the left apex in front, and expiration prolonged over the right upper scapular region. The appearance and action of the vocal cords were normal. There was no specific history; the patient was married, but childless, and had had no miscarriages. She had a severe attack of rheumatic fever at the age of twenty, and thinks she strained herself some four and a-half years ago while engaged in house cleaning. A year later a continuous, dull, aching pain in the right side of the chest began to trouble her, and on examining the part she discovered pulsation and swelling. She was admitted to the Middlesex Hospital, and remained there from January 22 to July, 7, 1879, being treated with gradually increased doses of iodide of potassium, confined strictly to the recumbent position, and dieted on the plan advocated by Mr. Tufnell. After nearly six months of this treatment she was discharged much relieved, being free from pain, and with diminished pulsation in the aneurism. There was, however, no evidence of consolidation. Since her discharge she had continued to attend the out-patient department. Comparing her condi-

tion on physical examination when in the hospital, with what it is now, the following differences appeared. At the former period the diastolic sound over the tumour was accompanied by a "thud," indicating the competent closure of the aortic valve; the situation of the apex beat was normal, and the heart's sounds there were unaccompanied by murmurs. Now the thud has disappeared, the apex beat is somewhat outside its normal position, and there is a murmur at the apex both with the systole and diastole. The pulsation in the tumour, too, feels more superficial now than it did then. From this comparison the sequence of events seemed to be, weakening of part of the wall of the aorta in connection with the attack of rheumatic fever, and its giving way under the strain referred to; then the gradual dilatation of the aneurism leading to incompetence of the aortic valve, and this, in turn, to dilatation and hypertrophy of the left ventricle, with mitral incompetence. The question for consideration now, seeing that medical treatment had so far failed, was whether it would be proper to resort to operative procedure, and if so, what that procedure should be. Galvano-puncture might commend itself to some; the distal ligature, as exemplified in cases recorded by Dr. Cockle and Mr. Heath, Mr. Holmes and Mr. Barwell, and to others. There seemed to be points in the case both in favour of and against operative interference. In the former category might be mentioned the youth, good general health, circumscribed appearance of the aneurism, and absence of pressure signs. On the other hand there were the nearness of the aneurism to the aortic orifice, and the aortic regurgitation, which would expose to the danger of portions of clot being washed back into the left ventricle, together with a greater risk than in cases where the valve was competent, of clots being detached and carried forward in the other direction. At the same time the regurgitation might be slight, judging from the small amount of dilatation and hypertrophy. Altogether the *pros* and *cons* seemed so equal that it was difficult to strike a balance in favour of either side; all the more so when it was considered that the patient was not unlikely to live for a considerable time in fair comfort without surgical treatment.

Dr. DOUGLAS POWELL remarked that the case opened up many important questions as to treatment. Of primary importance, however, was the accurate diagnosis of the tumour. He agreed in thinking it a sacculated aneurism, and that, surgical interference should be resorted to with the utmost caution. This would be favoured by the marked improvement of the case while under treatment, although there was evidence of a good deal of subsequent melting away of the consolidation set up, and it was to be anticipated that perforation would sooner or later ensue. The condition of the aortic valves was an important matter to be considered, for if regurgitation was made out with certainty, then operation could be attended with small benefit. He was himself inclined to think the second murmur was purely aneurismal, a view also favoured by the fact that, though sensibly heard generally, it was much louder above and to the right than towards the epigastrium and apex, thus reversing the usual signs. The marked *thrill* likewise suggested the same conclusion. The condition of the valves would entirely guide a decision on the question of operation. The illness seemed to date from an injury received shortly after recovery from rheumatic fever, which latter might have left the aorta weakened.

Dr. DE HAVILAND HALL had never seen galvano-puncture resorted to in more than one case, when it was employed too late. The patient was under the care of Dr. Hughes Bennett; the aneurism in size and position resembled the one under discussion. On admission into hospital there was a red point over the skin at one spot. Patient at first refused, but subsequently submitted to galvano-puncture. He died, and at the post-mortem examination a certain amount of laminated deposit was found, but also a tract of suppuration at the point where the needle had been introduced. From signs observed, however, it was probable that much earlier operative procedure might have saved the patient's life. The case had been recorded in the Proceedings of the Medical Society about two years ago.

Dr. LONGHURST thought the case showed that the essence of treatment was *rest*, which also was the object sought to be attained even by the ligature, or by pressure. It was, indeed, secured by various means, but was always the prime object of treatment. Any operation in Dr. Finlay's case was, in his opinion, out of the question.

Dr. T. WILLIAMS said he formerly had a male patient under

his care in the Brompton Hospital who presented a very similar tumour to that in Dr. Finlay's case. The anterior wall of it became at one time so thin that rupture seemed imminent, but under rest and reduced diet it became much thicker, and the patient got better and returned to work. Subsequently the aneurism wall again thinned, and eventually it burst, not however, in the part concerning which fears were originally entertained, but at a spot quite removed from it, and situated posteriorly. He would be glad to hear if other observers had noticed any similar occurrence.

Dr. HENRY GREEN asked if the tracing exhibited by Dr. Finlay, and taken from his patient, did not reveal the condition of the aortic valves. In two cases of sacculated aneurism under his own care, galvano-puncture had been employed. In one, no effect was produced; in the other, slight diminution in the pulsation ensued.

Mr. HOWARD MARSH said cases of aneurism of the arch of the aorta were on record in which much benefit was derived from treatment by rest. He instanced a case of large aneurism of the arch preserved in the museum of St. Bartholomew's Hospital. It occurred in a man, and by rest the pulsation in it was much reduced. Patient, however, after leaving hospital, got into a drunken row, and returning, died. Post-mortem examination showed the tumour to be so much improved that, with care, life might have been considerably prolonged. Last year he had under treatment a patient with aneurism of the innominate whose condition was much improved by rest, low diet, and the application of ice to the tumour. The aneurism, notwithstanding, enlarged, and ligatures were then put upon the carotid and subclavian arteries. All went well, so far as the wounds were concerned; and the aneurism solidified on one side, but grew rapidly in another direction, and at length reopened the two ligatures. This tended to confirm Dr. Williams' statement, that such tumours did not usually burst through the skin, and that operation was not likely to benefit them. Perusal of cases showed that, though the distal ligature produced such remarkable results, duration of life afterwards only averaged two years, the greatest length being no more than four years. Failure might, of course, be said to be due to the fact that such proceeding was adopted only in desperate cases. Dr. Finlay's case seemed to be a favourable one for operation by ligature of the subclavian and carotid arteries, which, too, would be a justifiable measure in it. Antiseptics made such operations perfectly safe, and the improved ligatures recently introduced also tended to minimise the mere surgical risks. Distal ligature ought to be done at an early date of the disease. Galvano-puncture seemed always to fail.

Dr. FOWLER said he had carefully examined Dr. Finlay's patient, and was inclined to think the bruit heard was in part due to aortic regurgitation. He had conducted a post-mortem examination of the patient mentioned by Dr. De Haviland Hall, and his conclusion had been that the coagulation found was probably *not* due, except in a very small part, to galvano-puncture. In the course of the needle a black and charred clot was seen. He had made a post-mortem on only one patient treated according to Tufnell's plan. In this case death occurred from rupture of the aneurism, and no clot was discovered in the tumour. Were Dr. Finlay's case under his care he should not pursue further treatment of it.

Mr. PARKER suggested that the unreliability of galvano-puncture was probably due to the faulty construction of the apparatus employed. Deficiency of the current produced by batteries ordinarily used was the explanation he was inclined to offer in regard to the negative results obtained with them. He advocated increased attention to this matter before finally condemning galvano-puncture as a remedial agent.

Dr. POWELL observed that the case under discussion was a favourable one for affording information as to the value of the indications afforded by sphygmographic tracings. He did not think the tracings exhibited, showed any signs of aortic regurgitation, they were typical of aneurism.

Mr. WALSHAM considered the case a favourable one for operation, but he failed to see that ligature of the carotid and subclavian arteries would be of much use except in aneurism of the innominate, or when that vessel was partly involved. Perhaps Dr. Finlay's patient might be best treated by rest, however.

Dr. SILVER having made some remarks in reply to Mr. Howard Marsh,

The PRESIDENT nominated the following committee to

examine and report on Dr. Finlay's case:—Dr. Finlay, Dr. Douglas Powell, and Dr. Henry Green.

Dr. FINLAY said the main point for consideration was the existence or not of aortic regurgitation. He did not think galvano-puncture wholly out of the question.

SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society of Ireland was held on Friday evening, January 27th, in the Albert Hall, Royal College of Surgeons.

Dr. BARTON, Vice-President of the College, in the chair.

Mr. TUFNELL, Hon. Sec., read the minutes of the previous meeting, which were confirmed.

PRESENTATION TO MR. B. WILLS RICHARDSON.

The VICE-PRESIDENT: Gentlemen,—Owing to the unavoidable absence of the President of the College this evening, it becomes my duty to take the chair, and very glad, indeed, I am to do so, as it affords me the great gratification of acting as your mouth-piece in expressing to my old friend and colleague, Benjamin Wills Richardson (hear, hear), our best feelings of heartfelt esteem and affection. (Hear, hear.) The importance to such a Society as ours of an efficient, able, and courteous Secretary can scarcely be over-estimated. (Hear, hear.) We all know that authors are proverbially sensitive, and sometimes when the productions of their genius are brought forward for publication here or elsewhere, it may be a difficult matter, requiring a great deal of tact and temper, to arrange the knotty points that arise. We also know what a trifle would turn the scale with all of us between the trouble of writing out our cases and presenting them here, or preparing a paper and declining to do so. But to overcome all these difficulties and objections the duty devolves on the Secretary, who must not on any account ever be tired or cross, and must always be good-tempered, courteous, efficient, and firm. Such was the office Mr. Richardson undertook to fill for this Society twenty-five years ago (hear, hear); and I may say that it is to mark their appreciation of the manner in which he has performed his task that the members of the Society desire to make him a presentation to-night. (Hear, hear.) He proved himself invariably punctual, business-like, courteous, and firm, combining in a remarkable degree the *suaviter in modo* with the *fortiter in re*. (Hear, hear.) How far the success of the Society may have depended on his exertions during the long period of his tenure of office it would be hard to say; but having been associated with him for many years in another institution, I must decidedly say that a more thoroughly practical, able, courteous, and efficient Secretary it would be impossible for us to secure. (Hear, hear.) And now, Mr. Richardson, it becomes my pleasing duty, which, as I have already stated, I am gratified to be in a position to perform, to ask your acceptance of this service of plate which the members of the Surgical Society of Ireland desire to present as a small token of their heartfelt esteem and affection, and, at the same time, to express through me their earnest wishes for your health and happiness. (Applause.)

Mr. RICHARDSON, in reply, said: Mr. Vice-President and gentlemen,—It must always be gratifying to a professional man to feel that he has won, and enjoys, the confidence of his brethren; and when this confidence becomes, as it were, incorporated with the material out of which this very valuable and beautiful testimonial has been fashioned, and which you, Sir, in the absence of the President of the Surgical Society of Ireland, the representative of those with whom the Honorary Secretary had been for so many years associated, have presented to him in most flattering—but he fears—too eulogistic language, he would be stolid, indeed, were he not more or less unshingled by these proofs of good feeling towards him. Such, Mr. Vice-President, is my embarrassed position at this moment. Believe me, Dr. Barton, that it was not without prolonged reflection I determined—most reluctantly determined—to resign the honorary secretaryship of the Society, and thus dissociate myself from Mr. Tufnell, whom I have always found ready to assist with his advice and active co-operation. But I felt that new and imperative demands upon my time would prevent me from attending to the duties of the office so actively as I had hitherto done, and that the interests of the Society would most probably suffer thereby. Hence, Sir,

my resignation of the post. It is satisfactory, however, to know that the Society cannot, for lack of energy, possibly retrograde by the resignation, my friend and successor, Mr. William Thomson, being pre-eminently endowed with the qualities the secretaryship requires, so that Mr. Tufnell is to be congratulated in having gained the assistance of one who is so distinguished, you are all aware, for his literary, as well as for his surgical, acquirements. I again thank you, Mr. Vice-President, and the members of the Surgical Society of Ireland, for this tangible evidence of your and of their esteem, which I have no doubt will oft arouse in the mind of its possessor in the future, a memory of the kindness and fellow-feeling so eloquently elaborated by you, Sir, and so warmly echoed by this meeting. (Applause.)

MORBID SPECIMEN—FRACTURE OF THE ASTRAGALUS.

Mr. HENRY GRAY CROLY exhibited fragments of a fractured astragalus, of which he believed there was only one specimen in the museum. The man from whom they were removed met with the injury by a horse falling on him and catching his foot in the stirrup, so that he sustained a compound fracture which penetrated the joint. There were two large sinuses—one of the instep and the other under the ankle. He explored the sinuses, and finding the fragments, he removed them. The limb was already in a useful condition.

Mr. THORNLEY STOKER read a paper on

THE RADICAL CURE OF INGUINAL HERNIA,

which will be found on page 157.

The VICE-PRESIDENT remarked that the subject was one of the highest surgical importance and interest as regards the advance of science. He had witnessed Mr. Wood operate last summer by his own method, which was exceedingly interesting; and the results of his experience were as had been stated by Mr. Stoker.

Mr. H. G. CROLY thought he had the advantage of seeing the first Wood's operation in Dublin performed by the late Prof. Morgan for the radical cure of hernia, and notwithstanding the freedom from serious symptoms in most of Wood's cases, in that case very dangerous peritonitic symptoms followed the operation, so as to alarm Prof. Morgan. Wurtzer's operation had been performed some years ago by Mr. Tufnell, but it was not a very certain one to effect a radical cure. However, having seen the patient the other day, the result was perfect—the man had not the slightest tendency to hernia. He had not read any published cases of the radical cure of hernia by dissection, but he had himself, in the City of Dublin Hospital, performed four operations for the radical cure by that means. Everybody was aware of the difficulties attendant on Wood's operation, and few students came away from lecture or clinique who understood it. As to the four cases in which he had operated by dissection, one was that of a child, 18 months old, with a very large hernia. He had the hernia reduced and kept in the abdomen. Then, under the spray, he dissected down as in the operation for the relief of strangulated hernia, and he invaginated the sac into the ring, stitching the pillars of the ring together in such a way that it was entirely closed. The result was perfect; the child had not the slightest tendency to rupture. In the case of a man, the rings were so enormously open that no operation could effect a perfect cure, but he expressed himself greatly relieved by it. From an experience of three or four cases of the radical cure of hernia by dissection, he did not mean to say that that method of treatment had decided advantages over Wood's operation. What seemed to him to be the advantage was that, as in the operation for strangulated hernia, the surgeon cut down from the external ring directly over the tumour and could thus see every step of the operation. The operations were generally conducted with antiseptic precautions; but from the experience he had gained of the dissection method, he felt inclined to continue it.

Mr. A. H. CORLEY said they could scarcely over-estimate the importance of the question of the radical cure of hernia. In the Richmond Hospital there were exceptional opportunities of seeing cases of hernia, the Truss Institution being there. From what he had seen, he thought that under modern scientific and especially antiseptic precautions, the operation of dissection offered a better chance of a more complete cure and less uncertainty than Wood's operation. He had no experience of that operation himself; but it seemed to him, from what he had read of it, that it was, on

the whole, a most scientific operation for the radical cure. The ordinary operation for hernia was not attended with danger to the patient, and early operation would be undertaken under the best possible conditions for recuperative action. By dissection there was the advantage, as Mr. Croly had pointed out, of seeing what he was doing instead of feeling with the tips of his fingers. Perhaps this was the crucial test, that if he wished an operation performed on himself, he would prefer having it done by dissection rather than the mode so admirably described by Mr. Stoker. Even in the most educated and practised hand the use of Wood's needle might be attended with undesirable consequences.

Mr. WHEELER said he found, as stated by Agnew, that of Gerdy's sixty-two cases, four died, and there was no means of knowing how many were cured. Dr. Weber had stated that of fourteen persons operated on by Wurtzer not a single case was cured, while Agnew, speaking of his own method, said he could only do so with distrust. Mr. John Wood, of London, had operated 155 times, with the result of 40 failures, 2 deaths, and 113 cures; but the duration of the so-called cures had not been ascertained. The results mentioned by Mr. Stoker were somewhat different to those he had quoted from Agnew's work, published in 1878. With regard to the dissecting operation, it had been proposed and adopted a long time ago. Mr. Richardson had alluded to it in the *Dublin Journal* in a review of Gross's work. The operation was performed in this city many years ago by the late Mr. Walsh, surgeon to the Adelaide Hospital. Hence, there was nothing new about it. When operating, most surgeons did so antiseptically—he used the term in contradistinction to Listerism; but even were he himself a follower of Lister, he would not use the spray in operating for the radical cure of hernia. The reason the operation was not often followed by peritonitis appeared to be that the character of the peritoneum was changed in old hernie. He thought that cases would require long-continued observation before it could be positively asserted that the hernia had not returned and that the case was cured.

Mr. STOKER replied. He said the reply to most of the remarks requiring an answer was anticipated in the views already expressed in his paper. There could be no doubt that Mr. Croly had carried out the procedure himself without any knowledge of simultaneous or prior action having been taken abroad. He quite endorsed what Mr. Croly had said, so far as his own limited experience went, concerning the difficulty of the operation. Both Mr. Croly and Mr. Corley had dealt with the question of selecting the operation by dissecting instead of that of Wood. For himself, he avoided expressing any definite opinion on the matter, regarding it as very much *sub judice*. Wood had operated on 200 cases. The list was unstained by a death from any cause whatsoever. Until he (Mr. Stoker) saw a series of cases of operation by dissection equalling Wood's in length and result, he was prepared to follow Wood's method. If the operation by dissection afforded equally good results he would choose it in preference to Wood's, because it was a much easier procedure, and therefore one that could be more widely adopted. They would all do an easy, rather than a difficult, operation, and a certain, rather than an uncertain, one.

Mr. WILLIAM STOKER then read a paper on the "Division of the Neck of the Femur in Cases of Anchylosis." The discussion on it was postponed to the next meeting, and the Society then adjourned.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

MONDAY, FEBRUARY 6.

Mr. S. LEE RYMER, President, in the chair.

ALVEOLAR PERIOSTITIS IN DIABETES MELLITUS.

Mr. HENRY SEWILL called attention to a communication recently made by Dr. Magitot to the French Académie de Médecine, in which he stated that alveolar periostitis was always met with in the mouths of patients suffering from diabetes mellitus, and was therefore of great assistance in forming a diagnosis of that disease. He had himself met with two cases which appeared to bear out the correctness of this observation, and he should be glad to hear if others

had met with the same experience. He also mentioned the case of a young gentleman who consulted him about a small cavity in an upper molar. Whilst Mr. Sewill was preparing the cavity for stopping, the patient had two short but distinct epileptic attacks. Mr. Sewill remarked that the nature of these attacks in the early stages of epilepsy was often unrecognised by the patient and his friends, and it was therefore the duty of any practitioner who might observe them to give timely warning of their true import.

Some other cases of interest having been brought forward by Messrs. S. J. Hutchinson, Henry Moon, Browne-Mason, and Dr. Campbell, the President proceeded to deliver his Inaugural Address.

PRESIDENT'S INAUGURAL ADDRESS.

After thanking the Society for the honour it had conferred upon him by electing him to his present distinguished position, Mr. Rymer referred to the recent alteration in the bye-laws, which enables the Society occasionally to elect a president from among the provincial members—a change of which he had been the first to reap the advantage. Mr. Rymer then went on to speak of the part taken by the old College of Dentists in the Reform movement of 1856 and following years. This institution, in the management of which he had, as secretary, taken a very active part, had been established for the purpose of carrying on the education and licensing of dentists on an independent basis, it being thought that too strong a feeling existed in the medical profession to allow of the institution of examinations and the issue of diplomas in a speciality of any kind by any of the medical corporations. When, however, it was announced that the College of Surgeons, after long deliberations, had come to the conclusion that it would tend to the public advantage to grant diplomas in dental surgery, and the code of regulations was published, the duty of those who had the direction of the affairs of the College of Dentists at once became clear. To have continued the College on an independent basis would have been unwarrantable under the circumstances. Instead of helping on a good cause, it could only have carried on an embarrassing opposition, and postponed indefinitely the attainment of fraternal concord. Communications were accordingly opened with the Council of the Odontological Society, which had throughout favoured the establishment of the dental as a branch of the medical profession, with the view of arranging an amalgamation. This was soon consummated with entire cordiality on both sides, and he had no hesitation in saying it had never for a moment been regretted. Had the profession continued to be racked with wide-spread dissensions the Dentists' Act of 1878 would not have been secured. As it was, the opposition to the measure arising from a small section of men with impracticable views, was easily overcome. This was unquestionably the most important event which had happened during the twenty years which had elapsed since the amalgamation. Its healthy action had already become apparent, but it would require some time before all its latent powers could be fully developed. Its elevating influence would increase with each succeeding year. Mr. Rymer then spoke of other signs of progress in the profession—of the growth of the British Dental Association, the establishment of new schools in the provinces, the flourishing condition of the dental societies, and the progress of dental literature and journalism, and concluded by referring to some of the unsolved problems still before the profession, the most important being a clearer knowledge of the conditions which would favour longevity in the dental organs.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their population were:—Birkenhead 14; Edinburgh 18; Derby 19; Leeds, Cardiff, Birmingham, Bradford, Halifax 21; Leicester 22; Sheffield, Hull, Norwich, Huddersfield 23; Bristol, Sunderland, Plymouth 24; Nottingham 25; Salford 23; Liverpool, Preston, Wolverhampton 27; Bolton, Glasgow 28; Newcastle-on-Tyne, Oldham 30; Manchester 32; Dublin 33; Blackburn 34; and London 35.

THE TREATMENT OF INTERNAL ANEURISMS.

AT no period in the history of medicine, probably, has general attention been given to the consideration of therapeutic measures with results so prolific as are being obtained at the present time. Whether regard is had to the significance of failures in treatment, or to successes achieved, we are at once forcibly struck by the value of the information that is daily adding to our stores of knowledge; and to whatever cause we may be disposed to assign the undoubted impetus the spirit of discovery and the effort after improvement have received, we are equally compelled to recognise the importance of the advances constantly made. The last few years—indeed, one might with truth assert the last few months—have been extraordinarily fruitful of great improvements in both medicine and surgery. Our own pages bear ample testimony to this fact, and it is a source of the highest gratification to us that no inconsiderable share in them has been taken by British representatives of the profession. There is, however, one subject of which it cannot be said that so much has hitherto been accomplished as will suffice to give it a prominent place in the list of diseases conquered by modern improvements in treatment. Notwithstanding the earnest attention paid to cases of internal aneurism, and the skill and ability brought to bear upon them, they still remain among the affections least amenable to curative agencies. That this is felt to be a matter calling for strenuous exertions, there is, however,

ample testimony forthcoming; and we may be permitted to anticipate ere long the introduction of measures which will be of effectual service in dealing with these intractable tumours. In the past they have always been regarded with grave suspicion, and with reasonable cause. We need only recall for a moment the nature of the remedies employed in the attempts to remove them to perceive this truth. At one time Val-salva's heroic treatment was almost the sole resort of physicians, and extensive depletion, together with rigorous starvation, were trusted to as the sole possible agents of cure. From this to Tufnell's system, the prominent features of which are rest in the recumbent position, and a very moderate diet, with sparing supply of fluids, was an inestimable advance, and under it very many cases of undoubted improvement have been recorded. The majority of patients, however, do not maintain the benefits derived during continuance of the treatment, and even the most marked instances of improvement are by no means the least probable of reversion to a hopeless state. Perhaps more genuine advantage has followed the introduction of the iodide of potassium treatment than any other; and although we are unable to look on the drug as a specific remedy, not a few of the most prominent physicians regard it with a confidence begotten of the results achieved with it in their experience. Certainly very many cases do well under it, and coagulation of the contents of the aneurism, either partial or complete, rarely fails to follow its employment. It may well be questioned whether the drug has yet received so full and thorough a trial as it deserves; whether it is not unfrequently too soon discarded or reduced in amount, because of the inconvenience caused by its administration. Except in large doses, it exerts very little beneficial effect, and hence it is commonly considered a hopeless task to push it to advisable limits. In this connection, therefore, it cannot be too widely known that free dilution of the salt prevents the occurrence of unpleasant after-consequences; and that, provided it can be given in sufficient amount, it may be trusted to alone for the production of desired changes in the aneurismal tumour. Where it is decided to strictly limit the quantity of fluid ingested by the patient, it is, of course, impossible to prescribe such dilution of the medicine as is suggested; but if, as we are taught by, among others, Dr. Balfour, the iodide is capable of bringing about the necessary changes unaided even by rest, then dilution is easy to secure. The exact mode of action of the drug is undetermined. The effect it produces is certainly coagulation of the blood within the aneurism; and equal difficulty attends explanation of the changes set up by ergotine when subcutaneously injected. This last remedy, however, meets with few supporters. In some cases it has produced good, but more frequently it has been tried in vain. Nor can we be surprised, for ergotine acts energetically on the hollow muscles; whereas, in a sacculated aneurism particularly, muscular tissue is the least well-developed structure of its walls. At best the remedy was experimental; its inadequacy has been sufficiently proved.

Whatever value may be ascribed to the various

methods of treatment above referred to, it must yet be admitted that surgical measures are alone competent to deal successfully with many cases of internal aneurism, although there are not a few in which the surgeon is powerless to offer aid. The ligature, compression, and galvano-puncture are now the three agents to which we have to look in this connection; but the second—compression—is, for obvious reasons, capable of employment in a small proportion only of these tumours. Ligation of the arterial trunk beyond the tumour has been successfully practised in many instances, and in examples of aneurism affecting the primary vessels springing from the aorta it is likely always to yield good results. The first consideration of all treatment in this class of diseases, viz., slowing of the blood current and promotion of the coagulating process, are thereby most surely effected, and we are justified in assuming that any case would yield to such treatment, provided it is adopted at a sufficiently early stage. The futility of the most successfully performed operation of this kind, where delayed too long, has again and again been shown by the condition of the aneurismal sac, which frequently bursts at a distant spot from that first threatened, the degeneration set up having been too extensive to admit of its being altogether controlled. On pathological grounds there is nothing to urge against the probability of long-extended life following such operations when performed at an early date. Much of the non-success hitherto attending them is chargeable to the desperate condition of the patients at the time it has been performed.

Galvano-puncture for aneurism may be said to be on its trial. Disappointment has followed its use up to the present in the experience of most operators, but we are inclined to agree with a suggestion recently made, that this is the fault of the apparatus rather than of the agent employed. Effectual currents need to be of a definite and constant strength; greater than that obtained by the four-cell Daniell battery ordinarily employed. It has been urged that a six-cell current produces an amount of pain which is intolerable. This indicates not that galvano-puncture must be discarded, but that it must be carried out with the assistance lent by anæsthetics. Again, frequent failures, if traced to the actual cause, would be found to be due to faulty construction, or to inattention to some point of essential importance in electrolytic operations. All these details are worthy of, and should receive, careful attention ere the treatment of dangerous aneurisms by galvano-puncture is finally abandoned. We cannot believe it will be found of such little service as has been described, and shall look with interest for its vindication as a remedial agent in the future.

In all that has been said in the foregoing paragraphs the questions of diagnosis, and of the nature of the aneurism as affecting treatment, have been intentionally avoided. We have endeavoured briefly to indicate the present position of our knowledge in regard to these tumours, and the mode of dealing with them; and, much as this may call forth a wish to witness a more rapid improvement in the particular direction referred to, we still consider that recent events point conclusively

to the probably speedy realisation of our best hopes on behalf of the treatment of internal aneurisms.

OUR COLLIERIES.—III.

In the good old days of some four-score years ago, when men, women, and children worked in, or more correctly speaking, *inhabited*, the mines, Sanitary Acts were little thought of. Nor were the ordinary usages of the time such as to require them. Once every year, in the early spring, the "hiring time" came round, when the yearly "bond" was read; and then followed rush and crush of men to sign it, the first of those to sign receiving any sum from a sovereign to five pounds, and beer *ad libitum*, and boys and children in proportion. The terms of the "bond" insured on the one side constant service to the master, and on the other, full employment and a home and fuel for the family for a year in advance; and that completed the matter. Accidents, entailing injury, while at work, were provided for by the employment by the mine owner of a "colliery doctor;" and the men "saved up" for sickness as they chose, or as best they could. Fevers and small-pox came and went, raged, abated, lingered, and returned, and at length departed. The stricken ones died or convalesced. There was mourning and there was rejoicing, and there was the usual modicum of "drink" at either.

And so the years wore on. Before the days of Watt or Bell, Stephenson or the historic and philosophic tinker who discovered the power of steam, coals for home or foreign use could be purchased at much less than forty shillings a ton; and the gross tonnage "drawn" out of the pits was, probably, not a five-hundredth part of that of to-day. In those days mining villages were not considerable towns, and if the houses were small the demands upon their space did not call for the inhabitants sleeping by "double shift." And similar needs governed the closet, sewerage, and water supply. But a time came when all this was changed; and with the growth of trade and increase of population, new habits and customs, new manners and new laws, arose, and the whole situation of affairs everywhere was changed. That it was the design of the Legislature to be vigilant over the nation's health goes without saying, when we remember that in twenty-three years—namely, from 1855 to 1878—no less than fourteen Acts of Parliament (for England alone) were passed for the very purpose of protecting it. The chief of those Acts (that of 1875) divides the whole of England (the metropolis excepted) and Wales into sanitary districts, urban and rural. And those districts are watched over by at least two officers in each—a medical officer and a nuisance inspector.

The appointing of these is vested in the local authorities—namely, town councils, local boards, and Poor-law guardians, subject to confirmation by the Local Government Board. This roundabout, unsatisfactory, and practically irresponsible system of appointment is open to grave objection in general, as we have before now pointed out; but in colliery districts in particular, the abuse rises to its acme. This can be seen at a glance when we disclose the method by which both Poor-law guardians and members of local boards are elected in those districts. We purposely

omit all reference to the particular colliery introduced in our opening article, and have, therefore, selected from our Commissioner's report the following details concerning an urban and a rural sanitary authority, which may be taken as fair examples of all. The total area of the two districts is about 16,000 acres (roughly, urban 1,500, rural 14,700), and the population may be set down as close upon 42,000 (urban, 14,600; rural, some 27,800). Two Peers of opposite politics are the chief land and colliery owners in the district; and the Board of Poor-law Guardians is composed, for the most part, of the farmers and colliery officials under each. There is, therefore, a much nicer balance of parties at the Board than the present House of Commons can boast of; and this state of affairs has its comforts and advantages unknown in the grand assembly. No tyrannical majority seeks to impose silence upon the minority by the argument common to all mobs—namely, brute force; and no minority taunts the majority with bringing ruin and disunion upon the Union. Thus, Lord A. and his men practically can do as they like in the south, while Lord B. and his men enjoy a similar liberty in the north. The sanitary medical service (which is dual) follows this rule exactly, both as to mode of election and discharge of its functions; and the nuisance inspectorship for the rural being in the singular number, when a vacancy occurs for this office both parties coalesce and elect the man who, from history and antecedents, will prove most harmless (i.e., least troublesome) and least actively offensive to all. And thus affairs glide along here most amicably: dirt, disease, and death follow as a matter of course; but then, "they are only colliers, and there are plenty of them."

How long this state of affairs may be allowed to drift on without a remedy will depend upon the interest taken in it by the country. At any rate, in opening it out, we have done our duty; and possibly, at some future time, we may be induced to return to it if remedial measures have not resulted. In the meantime something might, and ought, to be done, and we call upon the Local Government Board, in the interests of the public, the poor colliers and their families, to step in and discharge their bounden duty in defiance of the "vested interests" which foster these abominations.

JADED BRAINS AND WORRY.

Is human life lengthened by modern sanitation; by our efforts to improve the dwellings of all classes; by the crusade in favour of fresh air and fresh water; by the vigorous propaganda of the press, and even the pulpit, in diffusing what is called health education? Who can doubt the answer? It is sung out in pæans of joy at each sanitary congress; so much is added to human life by the saving of infant life; by the arrest of fevers of all classes; by the conservative surgery of modern times, and by the daring operations of our leading surgeons. There are, however, some pessimists—who have some truth on their side—who assert that all this saving is counterbalanced by the increased mortality, taking place from diseases of modern life, from worry—that essential feature of modern existence. What does worry mean? Is there such a thing? Is it

a neurosis? The pessimist says it exists. He points to the jaded, over-worked business man, who succumbs, at the age of 40 or 45, from some affection of the kidney, and he tells you that had it not been for worry this man would have lived to 70 or 80. But he has had too much to do. Anxieties of all kind, pressure of bills, large financial operations, requiring great thought and great waste of brain power, have been entered into. Sleepless nights have followed with loss of appetite and dyspnoea, and then kidney disturbance, with death, have put an end to all the useless strife for money or fame. He gives other instances from all classes of life, all proving that the pressure of modern times has a tendency to cut off, even in the prime of life; that jaded brains are produced, the churchyard reaping a rich harvest in consequence of this worry. He tells you, you save infant life—often not worth saving; that you bring up to boyhood or manhood the debilitated, the strumous, the deformed, but you lose at the most valuable part; that the deaths over 40 from modern diseases counterbalance the gain at the primary period.

The subject is a very important and interesting one. It is well that we should have some pessimists amongst us, otherwise we would indulge in optimistic dreams. If human life is saved at primary period, losing at middle stage, our plan must be to find out the best means of counteracting the loss.

Who can discover a remedy for worry? A return to Arcadian simplicity, to more primitive habits, simpler methods of living, to less striving after fame or money, would act as checks. But would life be worth living under the above conditions. How many would exclaim, "Better fifty years of Europe than a cycle of Cathay."

Notes on Current Topics.

Minor Hospital Appointments.

A CORRESPONDENT asked in our last week's number what was the best method of selecting candidates for the subordinate appointments in hospitals; whether by ordinary selection or competitive examination; and we invited the opinions of our readers on this important subject. A venerable anecdote is told of a man on his death-bed strongly advising his son to prefer honesty to roguery, adding significantly that he "had tried both." Being ourselves in this exact position as to making minor hospital appointments by selection and by competitive examination, we have no hesitation in expressing our condemnation of the latter. Professional knowledge is an important factor in the business; but there are factors of commensurate value; and we are not aware of any examination test which will pick out high character, kindness to the sick, and general satisfactory deportment. We have noticed that young men selected feel obliged to those that selected them; whereas those who obtained their places by examination appear to think that they are under no compliment for what was their right, and we have seen both classes trimming their sails accordingly. Of course, we speak on the supposition that the medical boards honestly endeavour to select the best candidates

all round, and do not convert the appointment into a mere nepotic or amicable job. We are glad to be fortified in our view by the high authority of the late Sir. D. J. Corrigan, who delivered an eloquent speech on this very subject in the year 1869 at the Statistical Society. He said, "We have now to consider the mode of election which has received the *ad captandum* name of 'concurus.' On my return from the Continent I was bitten by it, hoisted the standard of Excelsior, and said we must have the concurus. We had it; we got the worst men in the hospital, and in three years had to give it up. We found the men so appointed insolent to the other pupils, harsh and cruel to the patients, and intolerable to ourselves. We found, in short, that the man of talent and knowledge, who spent his time over the bed of his patient, and gave words of consolation and relief, was far better in an hospital than he who had read any amount of books." We endorse these words of wisdom and experience, and commend them to our more enthusiastic and progressive readers.

The Edinburgh Colleges and Dr. Lamson.

WE learn from the minutes of the Branch Medical Council for England, just issued, that the Colleges of Surgeons and Physicians of Edinburgh see nothing in the fraudulent appropriation of medical titles by Dr. Lamson to call for their notice. We quite anticipated that the Colleges would take this view, for it has always been their business to confer diplomas, not to revoke them, and they have never shown any excessive fastidiousness as to the character of the persons to whom they granted these licences. With them business is business, and money is money, and whether or not a licentiate obtains medical credit under false pretences is nothing to them, unless, indeed, that it relieves him of the necessity of buying the qualifications which he purloins. The case has now been returned on the hands of the General Medical Council, and we shall see whether the Council is more regardful of professional honesty than the Edinburgh Colleges.

Chinese Physicians.

ACCORDING to *Nature*, the Chinese authorities of Shanghai recently issued a quaint decree respecting the neglect of physicians to attend at once on their patients, and the high fees which they charge. They give notice that it is the duty of all physicians to use their knowledge for the benefit of the people; when people are sick they must be ready to attend upon them whenever they are sent for, without regarding the hour of the night or day, or the state of the weather. When people are ill they long for the presence of the doctor as the grain of seed longs for the rains. Instead of doing this, however, the physicians now think that they possess great skill, and not only charge high fees, but insist on being paid full hire for their chair coolies, and they do not care what becomes of the patient so that they get their fees. If these were only charged to the wealthy it would not so much matter; but the poor have to pay them also. An evil practice (the decree goes on) also exists by which doctors will not visit their patients before one o'clock in the afternoon; some will even smoke opium and drink tea until late in the evening. These are

abuses, the magistrates say, which they will on no account permit. Doctors must attend their patients at all times; they must, if necessary, visit them several times daily; they must think more of them and less of their fees. Notice, therefore, is given to all officials and people that a physician who does not attend when he is called must only receive half his fees and half his chair hire. "If you physicians delay your visits you show your wickedness, and sin against yourselves." The decree is a model one for a paternal government; argument, entreaty, exposition, threats, are all mingled in due proportion.

Castor Oil.

THE prospect of a castor oil famine is held out in a recent issue of the *Liverpool Journal of Commerce*, which publishes a series of figures to show that the stock at present held in this country and afloat for importation, is considerably less than was the case at the corresponding period of 1881. The following table explains the position:—

	Cases.
Quantity afloat for United Kingdom this time, 1881	27,681
Quantity afloat for United Kingdom at present	18,263
Decrease	9,418
Average consumption per month, 1881	
Liverpool	4,900
Consumption for month of January, 1882,	7,500
Increase	2,600
Stock in Liverpool on 1st February, 1882 ...	8,300
Afloat in ships now due	1,476
Total supply up to middle of March ...	9,776
Probable consumption up to middle of March	10,000

It is therefore probable that about the middle or end of March supplies will fall short of the demand, and as a necessary consequence prices will rise in proportion to the scarcity experienced. The outlook is sufficiently unsatisfactory; we can only hope that the expectations so freely expressed may not be verified, either by a diminution of consumption, or by early arrivals of vessels carrying castor oil as whole or part cargo.

An Amusing Instance of Journalistic Inconsistency.

ONE of the fiercest opponents of experimental science among the lay journals is the *Echo*, a cheap evening paper, one of the fixed beliefs of which, to judge from the nature of its articles on scientific questions, is that the "Anti" view is the one most worthy of support. Hence it is a constant occurrence to find its pages ornamented with reports of meetings addressed by anti-vaccinators, anti-vivisectionists, *et hoc genus omne*, while its readers are not ungenerously treated to editorials even penned in the same amiable service. It is therefore with a feeling of wondering surprise we find the *Echo* devoting nearly a third of a column to a jubilant description of the benefits to mankind produced through Pasteur's inoculation experiments on sheep and other animals. Can it be that the editor of the *Echo* has forgotten the mode of inquiry by which those results were obtained? or is it that he has

become convinced of the absurdity of antagonism to progress, and is resolved to sever the connection existing between himself and the party that employs his paper as a means of promulgating "Anti" views? It should be said, however, that the *Echo* has for long consistently denounced the torture of animals under the excuse of "sport," and we are glad to welcome the appearance of a determination on its part now to uphold the legitimacy of vivisection, or rather the experiments on living animals, as it undoubtedly does, indirectly, by accepting the value of Pasteur's discoveries.

Authorised Manslaughter.

IN a letter to the *Standard* of the 16th inst. a correspondent signing himself J. H. S. brings forward a charge of the heaviest kind against the Government, and one which, if substantiated, should create a widespread dissatisfaction. It is alleged that "about two months ago Captain Lambert R. Disney arrived in Omagh to succeed Mr. Mason as Governor of the County Goal. The drains in the Governor's residence were notoriously known to be faulty. One death and some illnesses had already occurred in Mr. Mason's family during that Governor's occupancy. Captain Disney, fully cognisant of this, very naturally applied for leave to sleep in lodgings until the drains under his rooms were mended. This leave was refused by the authorities. He was therefore forced to reside in this known pest-house. Luckily, he kept his wife and child in the town in lodgings. On February 7th Captain Disney died of typhoid fever, after a short illness, at the early age of forty."

Comment on this case, which is certainly an example of unprecedentedly cruel officialism, can hardly be made in terms strong enough to express the indignation evoked by a recital of the facts. It is particularly distressing, too, from the position held by the Government in respect to national sanitary affairs, and we cannot but hope that the matter is either exaggerated or misrepresented. Notwithstanding, however, there is great difficulty in comprehending how any mistake can have arisen; and in any case a searching investigation of the whole matter is imperatively demanded, and will, we trust, be directed to be made. Who are "the authorities" by whom the reasonable request of Captain Disney was refused?

University College Hospital.

AT the annual dinner of University College Hospital, held on Wednesday last, at the Langham Hotel, under the presidency of the Duke of Cambridge, the position of the institution was described as being somewhat depressed. It had been found necessary, according to the report, to sell out a considerable sum of invested capital to meet current expenses in the past twelve months; and much anxiety is experienced as to the future welfare of the charity. Several suggestions were made by those who spoke in proposing or replying to the toasts, with a view to remedying the existing state of affairs; among other things compulsory support of hospitals was hinted at as desirable, but nothing practical can be said to have been put forth. We heartily sympathise with the trouble the hospital is suffering, and trust it may prove but a temporary embarrassment, and that a measure of public sup-

port may speedily be accorded to it commensurate with its undoubted deserts.

General Medical Council.

At a meeting of Convocation of Oxford University on Wednesday last, Dr. Thomas King Chambers was elected to represent the University on the General Medical Council for a period of five years, in the room of the late Professor Rolleston. Dr. Chambers graduated M.D. in 1846, and has held the posts of Censor, Lumslean Lecturer, Gulstonian Lecturer, and Harveian Orator of the Royal College of Physicians of London. He is an Honorary Physician to the Prince of Wales, and Consulting Physician to St. Mary's Hospital. In him Oxford will possess a representative well calculated to maintain the high *prestige* of the University, and to guard its interests in the debates affecting its welfare.

Gastrotomy.

A SUCCESSFUL operation for gastrotomy is reported from Plymouth, Mr. Paul Swain having resorted to this procedure for relief of a woman suffering from malignant stricture of the œsophagus. So far it has been attended with most beneficial results; no bad symptoms supervened; and four days subsequently to the operation the stomach was opened, and the patient fed with warm milk and lime water. The case occurred in the South Devon Hospital.

Theatres as Sources of Disease.

At the commencement of another London season it may not be inexpedient to point out that many of our metropolitan theatres are so badly constructed and ventilated that they jeopardise the health of their patrons. Becoming greatly overheated and charged with foul air as the evening advances, they are swept at certain points by cold draughts, which are dangerous to all who are exposed to them, and which sometimes undoubtedly sow the seeds of fatal disease in delicate persons. Could accurate statistics be compiled, showing the mortality due to colds caught in theatres, the public would be startled into a peremptory demand on managers to set their houses in order. The number of deaths due to fires and accidents in theatres in any year—even in a year like that including the terrible Vienna catastrophe—is insignificant beside the figures representing the lethal effects of chills caught in theatres and their approaches. Managers should, therefore, apply their minds, not merely to facilitate the rapid egress of an audience, but to regulate the too rapid ingress of cold air; and visitors to theatres should resolutely decline to occupy seats in which they are conscious of a chilly current blowing over them. Invalids, and persons very liable to catarrh, had best stay away from theatres altogether, or only patronise them when their places have been selected for them by a professor of practical pneumatics. In one sense, the best theatres are the most hazardous to invalids, for whenever the emotional balance is disturbed, as it always is by a good and well-acted play, the susceptibility to the injurious influences of chilling of the surface of the body is enhanced; and, of course, the stalls and boxes suffer more from draughts than the pit and gallery, for those

who pay high prices of admission are less weathered and less sensibly clad than those who take their pleasures cheaply.

Perhaps the day will come when enterprising managers will place thermometers and anemometers in conspicuous positions in their houses, so that the public may satisfy themselves that their health is not being undermined while their fancy is being tickled.

Treatment of Persistent Vomiting.

PROFESSOR C. BRAUN, of Vienna, was lately called to a remote part of the Austro-Hungarian Empire to render assistance to a patient supposed to be dying of uncontrollable vomiting. As Prof. Braun reported in a lecture (*Wien. Med. Zeitung*, Jan. 31st), he found the patient, who was in the first half of pregnancy, in a very much reduced condition, and the practitioner in attendance considered that induction of premature labour would be necessary, owing to the persistence of the vomiting and the consequent rapid loss of flesh. As, however, Prof. Braun is no friend to the artificial induction of labour, he had the vaginal portion of the uterus bathed in a 10 p.c. solution of nitrate of silver. After five minutes this was well dried, so that no further caustic action should take place. The results of this procedure were so marked that in an hour the patient was able to partake of some roast veal, and after that no further vomiting took place. Generally speaking, Prof. Braun is of the opinion that hyperemesis will be removed from the category of indications for the artificial induction of premature labour, especially as he has often observed a fatal result after this treatment has been employed, but has never seen a death due to the persistent vomiting of pregnancy *per se*. Amongst the French, who are in the frequent habit of inducing abortion in hyperemesis, the vomiting ceases in only 40 p.c. of the cases, and in 10 p.c. death follows shortly after the abortion.

An Anæsthetic Mixture.

THE *Wien. Med. Zeit.* says that the Vienna mixture, under the use of which 8,000 operations have been performed without a single accident, consists of three parts of ether and one of chloroform; and Billroth's favourite mixture is composed of three parts of ether, one of chloroform, and one of alcohol.

THE St. John's Ambulance Association invite designs for horse ambulance wagons for town and country use. A medal and £10 10s. will be presented for the approved design.

IN consequence of the dense fog in London and suburbs on Saturday week, the Registrar-General reports a rise in the death-rate of 7 per cent. of the population during the week. This increased mortality was principally confined to persons of advanced age.

IN New York, scarlet fever and diphtheria continue to be fatally prevalent; no less than 109 deaths from these diseases were reported in that city last week. Diphtheria is also in excess in Paris, Berlin, and Glasgow, but not quite to the same extent.

Naphtol in the Treatment of Skin Diseases.

THE *Wiener Medizinische Wochenschrift* contains a series of articles by M. Kaposi, of Vienna, on this preparation and its applicability to the treatment of skin diseases, and as a substitute for tar. An endeavour of his to substitute some other body for tar, so much used in skin diseases, led to the discovery of naphtol. His experiments were guided by a fact, and by a certain theoretical conclusion therefrom. This fact is the well-known benefits resulting from the use of tar in diseased conditions of the skin as contra-distinguished from skin diseases, for the latter means a collection of symptoms which show themselves in the system, and receive a distinct name for themselves, and for which tar is not only useless, but injurious. The healing power of tar consists in its capacity for relieving certain distinct symptoms which are characteristics of disease. And the question to be decided is, for what symptoms, and at what time, should tar be used. Having pointed out the method of action of tar in these diseases, M. Kaposi dwells upon the disadvantages attending its use in consequence of its unpleasant smell, colour, and consistency. He remarks that objectionable symptoms are frequently developed from the absorption of the tar products into the general system, and considers that much would be gained if the principle which is active in the cure of skin disease could be isolated from the other elements of the tar, which are either useless or pernicious. With the aid of Professor Ludwig, M. Kaposi isolated it in the form of Naphtol, the beneficial principle of the tar product. This product he found to be very suitable for therapeutic use, being easily combined with fats for ointments, or spread upon linen for plasters. When applied to the healthy skin he found it to be a mild rubefacient of constant strength, and to be very effective in stopping the intolerable pruritus of skin diseases. The author gives in detail the results of his treatment of 106 patients suffering under numerous diseased conditions, and expresses his complete satisfaction with naphtol for this purpose, and the new agent appears to be fully established by him as an elegant and efficacious substitute for tar in these conditions.

RICHARD BARRETT, Esq., M.D., Carrigafooka House, Macroom, has been appointed to the Commission of the Peace for the county Cork.

WE are requested by the Council of the Odontological Society to give publicity to the fact that after November 1st, 1882, no application for membership will be received from any candidate not possessed of a diploma.

WE regret to record the death of Dr. Gadsby, of Mansfield, Nottinghamshire, at the early age of twenty-eight. Deceased was called upon to perform tracheotomy on a diphtheritic patient, from whom he caught the disease, and died a few days after.

THE amount to be raised by rates in London for the present year for the support of the Metropolitan Asylums and Fever Hospitals under the control of the Metropolitan Asylums Board is £226,076. There was a show of opposition at the meeting of the Board on Saturday, but the estimate was voted.

THE returns from the small-pox hospitals of the metropolis up to Saturday last showed a decrease of 46, and the fever returns a decrease of 26 patients remaining

under treatment, as compared with the figures of the preceding fortnight. The mortality from these causes is now exceedingly low in the metropolis.

As another instance of the overplus in our profession may be mentioned the fact that, for an appointment of surgeon to the Great Western Railway, with a salary of £600 a year attached, there were upwards of six hundred candidates. The appointment was decided last week in favour of Mr. Bond, Assistant-Surgeon to Westminster Hospital.

THE rates of mortality per 1,000 last week in the large towns from diseases of the zymotic class, were:—Scarlet fever 4.4 in Hull, 2.9 in Brighton, and 2.4 in Cardiff; from whooping-cough, 3.5 in London, 2.7 in Wolverhampton, and 2.5 in Huddersfield; from measles, 6.4 in Blackburn, 5.3 in Norwich, and 3.3 in Brighton; and from fever, 1.5 in Blackburn. The 45 deaths from diphtheria included 17 in Glasgow, 16 in London, 4 in Portsmouth, and 3 in Manchester. Small-pox caused 24 more deaths in London and its suburban districts, 2 in Bolton, one in Nottingham, and one in Hull.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 36, Bombay 30, Madras 46; Paris 36; Geneva 33; Brussels 24; Amsterdam 25, Rotterdam 29, The Hague 26; Copenhagen 27; Stockholm 21; Christiania 19; St. Petersburg 52; Berlin 23, Hamburg 29, Dresden 24, Breslau 28, Munich 37; Vienna 33, Prague 30, Budapest 39, Trieste 39; Turin 27, Venice 30; Alexandria 35; New York 32, Brooklyn 25, Philadelphia 27, and Baltimore 24. No returns were received from Rome or Naples.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

GLASGOW MATERNITY HOSPITAL.—Mr. Donald Munro has scored a triumph against the Chairman of the Directors of the Glasgow Maternity Hospital. At a recent meeting, Mr. R. R. Grant (the chairman) referred to Mr. Munro in terms which that gentleman did well to resent. He put the matter into the hands of his legal adviser, and the consequence is, that Mr. Grant has written to Mr. Munro a sufficiently apologetic letter, disclaiming any intention of reflecting on the personal character of the latter, and paying all expenses in connection with the case.

DEGREE OF SCIENCE FOR ABERDEEN UNIVERSITY.—The Senators of the University of Aberdeen have resolved to institute the degree of B.Sc. in connection with the University. The resolution will be brought before the next meeting of the University Court.

ABERLOUR, N.B.—Dr. Glass, who has practised in this district for the last two years with much ability and increasing popularity, was entertained to supper in the hotel on the 10th inst., on the occasion of his leaving for a lucrative appointment in India.

A FEVER EPIDEMIC AT MUSSELBURGH.—At the monthly meeting of the Musselburgh Town Council, held on the 14th inst., Provost Keir presiding, a communication was read from the Board of Supervision regarding a somewhat serious outbreak of typhoid fever which had occurred in Fisher Row, and suggesting the erection of an infectious diseases hospital as approved under the Public Health Act. It was agreed that a deputation should seek an interview with the managers of the Edinburgh Infirmary on the subject.

GLASGOW ROYAL INFIRMARY.—PRESENTATION OF AN ADDRESS TO MR. WILLIAM MCEWEN.—An interesting ceremony took place at the Royal Infirmary, Glasgow, on the 14th inst., in the presentation, by the nurses of the Institution, of an address to Mr. William McEwen, who has long taken a lively interest in its affairs. Dr. Thomas, Superintendent of the Infirmary, presided, and in a neat speech presented the address. Mr. McEwen expressed the gratification which the act afforded him, and stated that he had given 19 years' service to the Institution, and he hoped to be able, if spared, to give a few more yet, when he would continue to do all he could for the welfare and prosperity of the Royal Infirmary.

ABERDEEN COMBE LECTURES.—The fifth lecture of this course was delivered by Dr. Stirling, in Aberdeen, on Saturday, the 11th inst., to a crowded audience. The lecturer described and showed experimentally the mode in which food, such as flesh and milk, is digested in the stomach, and also how large a portion of the digestive act takes place in the intestines. The actions of bile and the other digestive fluids were all shown by simple experiments. The mode in which the food passes into the blood was illustrated also by experiments, which frequently elicited the hearty applause of the audience.

POISONOUS FISH.—A case of poisoning, supposed to have resulted from eating unwholesome fish, is at present being investigated in Edinburgh by Dr. Littlejohn and the police authorities. It appears that about nine o'clock on Thursday evening, the 16th inst., Dr. Gunn, Rankellor Street, was summoned to attend a family named Hastie, residing in St. Leonard Street, four members of which had suddenly become seriously ill. Dr. Gunn found that the sufferings of Mrs. Hastie and three children indicated the presence of an irritant poison. Remedies were immediately applied, but as the symptoms continued alarming, it was considered advisable to call in Drs. Jamieson and Moir. All the necessary antidotes were administered, but it was not till an advanced hour on Friday morning that the patients were out of danger. Mrs. Hastie, it seems, along with one of her children, had partaken of some fish (ling) about three o'clock in the afternoon, and both became ill. An hour and a half afterwards the other two children, on their return from school, also ate some of the fish, and the same result followed.

THE IRISH UNION OFFICERS' SUPERANNUATION BILL.

THIS measure was introduced into the House of Commons by Mr. Herbert Gladstone on Monday last. It is, we believe, in effect the same Bill as that drafted by the Irish Medical Association, with a few—not very vital—differences, which may possibly be the subject of amendments in its progress through Parliament. We shall lay it before our readers at the earliest possible moment.

THE NEW SCHEME OF EDUCATION AND EXAMINATION OF THE IRISH COLLEGE OF SURGEONS.

DEPUTATIONS TO THE HOME SECRETARY.

ON Friday last Sir William Vernon Harcourt, Home Secretary, received at the House of Commons two deputations from the Irish College of Surgeons in reference to this Scheme.

As our readers may recollect, the Council of the College has been for more than a year past at work on a reform of the educational system of the College, and that the Scheme which embodied this reform was worked out by the Education Committee of the Council, revised, paragraph after paragraph, by the Council itself, and, after adoption, submitted to, and approved by, the Fellows at large.

In all these stages the progress of the Scheme was resisted by a minority of the Council, and its final adoption by the College at large was the subject of a contest in which the supporters of that minority were outvoted. But the Scheme was in many respects at variance with the existing educational bye-laws of the College, which it therefore becomes necessary to annul, in order that the new regulations should come into effect, and for this annulment the approval of the Home Secretary was considered advisable, inasmuch as the College Charter makes such sanction necessary under certain circumstances. This sanction was purely formal; nevertheless, the defeated minority endeavoured to prevent the Home Secretary from according it, and forwarded to him a memorial praying him not to assent to the request preferred by the Council of the College. The result of this extraordinary and unprecedented proceeding was to oblige the Council, after a long delay, to apply to the Home Secretary to receive a deputation on behalf of the College, and that application being granted, at once the minority applied for an interview for delegates from themselves.

These deputations, as we understand, were received on Friday last. That from the College consisted of Dr. Chaplin, President, Dr. Barton, Vice-President, Dr. Kidd, Dr. Robert MacDonnell, and Dr. Jacob. That on behalf of the recalcitrant minority consisted of Dr. Mapother and Dr. Ormsby. It is, of course, not our function to forecast the result of these interviews, nor have we such information of the proceedings therat as it would be right to publish. We, however, expect to be able to inform our readers very soon as to the Home Secretary's decision respecting the confirmation of the New Scheme of Education and Examination. We cannot, however, refrain from saying that, in our opinion, the attempt to obstruct the Council in carrying the Scheme into effect, after it had received the thorough sanction of the College, was most unconstitutional, unprecedented, and unjustifiable, and will be all the more worthy of censure if even partially successful. The opponents of educational improvement cannot possibly defeat the contemplated reforms. They can only obstruct, as they have obstructed, and may still obstruct, but we do not think that they or their cause can be supposed to gain in public estimation by such tactics.

Literary Notes and Gossip.

"THE INFLUENCE OF VIVISECTION ON HUMAN SURGERY" is the title of a masterly and unanswerable vindication of scientific experiments in the cause of humanity, by Mr. Sampson Gamgee, of Birmingham. It is published, price one shilling, by Messrs. Churchill.

THE Anti-Vivisectionists have collected into a single volume all the nonsense written by themselves during the past year, and have issued it under the title of "Sixth Annual Report." As a monument of human weakness the bulky pamphlet possesses a not inconsiderable interest; as an example of the bigotry of ignorance it is appalling; as a literary composition it is amusing; as a reasonable objection to scientific progress it is worthless; as waste paper its value is likely to be higher than in any other direction, as it is very fairly printed on paper good enough to have been applied to better uses.

MESSRS. CASSELL, PETTER, GALPIN & Co. announce for publication on February 27th the first part of a new work entitled "*Our Homes*," which will consist of a series of articles dealing with sanitary and other details of house construction, written with a view to popular perusal. As editor the publishers have secured the services of Mr. Shirley Forster Murphy, Medical Officer of Health to St. Pancras parish; and among those who have undertaken to contribute to the work are Drs. Corfield, De Chaumont, W. B. Richardson, and Messrs. Brudenell Carter, Malcolm Morris, and Douglas Galton. The work is to be completed in twenty-four monthly parts.

THE *Ophthalmic Review* for February contains the continuation of Mr. Critchett's valuable "Practical Remarks on Cataract," which are followed by the first portion of a paper by Mr. Priestley Smith, on "The Action of Atropine and Eserine in Glaucoma." Dr. Wolfe's new book on the eye is reviewed in a not very enthusiastic style. The excerpts from Continental periodicals are especially interesting; and amongst them we find a paper of Pagin-stecher's on "Massage in Diseases of the Eye," and one on "The Pathogenesis of Cataract," by Deutschmann, of Gottingen. The report of proceedings of the Ophthalmological Society concludes the number.

AN essay on "Cancer of the Breast," by Mr. Nunn, Consulting Surgeon at the Middlesex Hospital, has appeared this week. It is divided into two parts—the first, Clinical and Practical; the second, Pathological and Speculative. But few men can have had such an experience in the treatment of cancer as has fallen to the lot of Mr. Nunn; and the work which he has now presented to the profession will be welcomed as one containing the latest known facts as regards the pathology, etiology, and treatment of this common and terrible malady. The work is illustrated by twenty-one exquisitely executed lithographs in colours, on the physical appearance and pathology of the disease. We shall refer to it in detail on a future occasion.

IN the new *Medical Register*, just to hand, for 1882 there are but few changes observable beyond the necessary alterations by death or change of residence. The work, under the editorship of Mr. Miller, has been gradually undergoing for the past three or four years such a radical metamorphosis that it has become a reliable work of reference, in place of the conglomeration of errors of former years. Simultaneously is published *The Dentists' Register* for 1882, under the same official auspices; but when we look through the pages of this latter at the motley crowd of educated and uneducated dentists, we cannot but deplore the passing of an Act which brought about such a mixture, and sympathise with the editor in his ungrateful task.

THE Fourth International Congress of Hygiene will be held at Geneva from the 4th to the 9th of September, 1882, and the Committee entrusted with its organisation by the State Council hope to make it worthy of its predecessors, the Congresses of Brussels, Paris, and Turin. Those particularly interested in hygiene and demography are invited, together with boards of health, scientific and sanitary societies, to submit as soon as possible to the

Managing Committee such questions as they may think worthy of treatment by the International Congress. Several essays have been already sent in, and an exhibition of books, plans, and instruments of all kinds concerning hygiene and demography will be held in Geneva during the whole of September.

AT the last general monthly meeting of the Royal Institution (February 6th), Mr. William Bowman, F.R.S., was elected Honorary Secretary, and Mr. Warren De La Rue, F.R.S., Manager. The latter gentleman has been compelled to resign the office of Hon. Sec., in consequence of declining health; and resolutions, expressive of regret at this event, and recognising the valuable services rendered by Mr. De La Rue to science and to the Royal Institution, were passed at a meeting held on December 16th, and read at the meeting whereat his successor was appointed. Mr. Bowman, whose contributions to medical and scientific literature are well known, may be expected to prove a most worthy successor to Mr. De La Rue in the post he has been elected to fill.

MESSRS. J. & A. CHURCHILL have recently published two highly useful tables of the average weights of the human body and brain, and of different internal organs at various periods of life. In one table are given the weights of normal beings, and in the other, those observed in cases of insanity. The tables have been compiled by Dr. Boyd from an immense number of observations, and the amount of most valuable information contained in them is very great indeed. In the second table, that dealing with the insane, the measurements of the head, as well as weights, are given; and the forms of insanity are described in a separate table. The sheets are mounted on card, and varnished, so that they may be hung for constant reference in the post-mortem room, where they will be found of incalculable service.

A SECOND EDITION of the *Report on the City Day-Census*, 1881, has been issued by Messrs. Longman. This volume, compiled under the direction of the Local Government and Taxation Committee of the Corporation of the City of London, contains a mass of information likely, in view of the approaching discussions in Parliament on City reform, to be of the utmost service in following the debates. It is printed in a handy form and is clearly arranged, and the various details are so classified as to render reference to any particular point an easy matter, this being, moreover, much facilitated by the addition of an excellent index. The book gives "Physicians, Surgeons, &c." in the City, as numbering 231; but further on it is found that these include chiropodists, phrenologists, analysts' agents, instrument makers, plaster makers, chest makers, dentists, &c., &c., so that it affords no real account of the City representation of the profession.

MESSRS. WILLS & WOOTTON, proprietors of the Westminster College of Chemistry and Pharmacy, have been taught during the past few days that they cannot insult literary men with impunity. In 1879 Dr. Belville was employed by them to write a Latin grammar for the use of their pupils, in which establishment he was also employed as tutor. Matters, however, did not go on quite smoothly, and in October, 1880, Dr. Belville was dismissed. Subsequently, Messrs. Wills & Wootton inserted an advertisement in the *Pharmaceutical Journal* which included the following paragraph:—"Dr. H. Belville has no more connection with Messrs. Wills & Wootton. We anticipate no failures in future." For this gratuitous insult the aggrieved party took an action for libel, which resulted in a verdict for him, with £100 damages. We hope Messrs. Wills and Wootton will, like their pupils, stoop to learn, and that this lesson will not be lost upon them.

WE are asked to announce that the Société Française d'Hygiène have issued the following subjects for competitive essays:—I. Hygiene and Physical Education of Children from Six to Twelve Years Old: Home Life, School Life, Country Life, and Life in the Workshop to be discussed separately. II. Personal and Domestic Cleanliness: a Study of Personal and Domestic Cleanliness of Rich and Poor of both Sexes and all Ages in Town and Country.

The rules applying to both competitions are:—1. The essays not to exceed 30—40 pages of printed matter in 12mo. 2. The essays to be sent, distinguished only by a motto, to the office of the Society, "30 Rue du Dragon, Paris," before September 1st, 1882. (Candidates who make themselves known in any way are excluded from the competitions.) 3. The successful essays become the property of the Society, and will be published either *in extenso* or in an abridged form; the names of all successful competitors to be in the title-page of the published pamphlet, which will be largely circulated. These two competitions are entirely distinct, and in each case gold, silver, and two bronze medals are offered.

AMONG the prizes in connection with the Paris Academy of Sciences to be awarded during the next four years, and of which a list has recently been published, are several for researches in medical science. The subjects announced include the following:—"Inoculation as a Prophylactic in Contagious Diseases of Domestic Animals," for the Vaillant Prize of 4,000 francs, and a medal. "The Cure of Asiatic Cholera," for the Breant Prize, consisting of the interest of 100,000 francs. "The Anatomy, Physiology, and Pathology of the Genito-Urinary Organs," for the Godard Prize of 1,000 francs and medal. For the Lallemand Prize of 1,800 francs, work on the nervous system is proposed. All these will be awarded in the present year. In 1884 the Sener Prize of 7,500 francs will be given for the best work on "General Embryology, applied as much as possible to Physiology and Medicine." The Dugate Prize of 2,500 francs will be given in 1885 for "Diagnostic Signs of Death and Means of Preventing Precipitate Inhumation;" and in 1886 the Jean Renaud Prize will be awarded to the author of the most meritorious work produced within the preceding five years.

The first volume of the "International Encyclopædia of Surgery" has just made its appearance, and we are thus enabled to form an approximate estimate of its ultimate size and value. The work is printed and published in America, under the auspices of Messrs. Wood & Co., the English agents being Messrs. Macmillan & Co. It is a royal 8vo, of about 700 pages, and is to be completed in six volumes, at one guinea and a half per volume (somewhat in excess of the American price). Various authors are requisitioned, and many old friends, in the way of illustrations are to be found scattered throughout Volume I., which opens with a translation of Stricker's "Disturbances of Nutrition," and closes with a chapter "On Amputations," by the editor, Dr. J. Ashurst, jun. Of the remaining fifteen chapters, twelve are by American authors, one French, and two English—Mr. Butlin and Dr. C. Mansell Moullin, who, with the utmost respect to these gentlemen, can hardly be considered as representatives of British surgery. Surely, in a work which claims international recognition, others than an assistant surgeon and an assistant physician could be found to represent this side of the Atlantic. We do not make these remarks in a captious spirit; it is with the word "International" we are prone to quarrel. That the work is illustrative of American surgery we take for granted, but European surgery, most certainly, No!

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last list, January 18th:—Clinical Lectures on Diseases of the Heart and Aorta, by G. W. Balfour, M.D. (2nd edition). Guy's Hospital Reports, edited by Mr. Howse, F.R.C.S., and Dr. F. Taylor (Vol. XXV.). Report of the Evidence of Howell v. West and Jones. A Plea for Early Ovariectomy, by G. G. Granville Bantock, M.D. Table II. of the Average Weights of the Human Body and Brain. Lectures on the Pathology and Treatment of Curvature of the Spine, by Wm. Adams, F.R.C.S. (2nd edition). The Other Side of the Opium Question, by W. J. Moore, L.R.C.P. Ed. Practical Exercises in Physiology, by J. Burdon Sanderson, M.D., F.R.S. St. Bartholomew's Hospital Reports (Vol. XVII.). Report of the Proceedings of the Fifth International Pharmaceutical Congress. Sea Sickness, by J. R. Stocker, M.D. Life Assurance (First Prize Essay), by T. M. Dolan, F.R.C.S. Sixth Annual Report of the Society for the Abolition of Vivisection. Report of the City Day-Census for 1881. History of Massachusetts, by S. A. Green, M.D.

International Encyclopædia of Surgery, edited by John Ashurst, M.D. (Vol. I.). On Cancer of the Breast, by Thos. W. Nunn, F.R.C.S. The Influence of Vivisection on Human Surgery, by Samson Gangee, F.R.S.E. On Hemorrhoidal Disorder, by John Gay, F.R.C.S. Opium-Smoking in America and China, by H. H. Kane, M.D. Materia Medica and Therapeutics, by Chas. D. F. Phillips, M.D. (Vol. II.) The Medical Register for 1882. The Dentists' Register for 1882.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 28 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

BUTTER.—The statement is authenticated by the highest testimony in every respect. For all purposes of food butterine is equally as serviceable as butter, although legally a fraud when used as an adulterant. You will find your other question fully answered in the "Current Topic" contained in our issue for Jan. 25, and which you refer to. We cannot undertake to promise space for your communication on any particular date.

A COUNTRY SURGEON.—Two guineas for midwifery is not at all an unusual sum, and many practitioners in country districts regularly receive no more. It is perfectly legitimate to regulate your fees according to the social circumstances of your patients; the very poor even should be attended gratuitously if it can be done without too much interference with other engagements. Doctors cannot help performing much unpaid duty; but we do not think they are the losers in consequence, all things considered.

MR. HARRISON BLYTH.—You should have no difficulty in procuring any form of midwifery forceps from an ordinary dealer in surgical instruments. Under the circumstances, however, you had perhaps better write to one or other of the well-known makers, such as Krohne and Seseman, Arnold, Matthews, or Weiss. Either of these names will forward a detailed price-list, from which you can order whatever you require. The case, though not unique, is interesting. Knots in the umbilical cord occasionally occur, and even without fatal results.

AN OUTSIDER mistakes the character of this paper. Application should be made to a medical practitioner, who will supply the information sought. We do not offer advice to non-medical readers in these columns.

MR. JAMES HENDERSON (Sunderland) will receive a private note.

MR. G. W. F.—You undoubtedly fell into unsympathetic hands; the money temptation was too strong for them to withstand.

E. S. T.—It is a curious case. Send a fuller and more complete account; with only the facts you supply at present, before us we are unable to say if a similar instance is on record. We rather think one or two closely analogous operations have been performed.

REDUCTION OF SULPHURIC ACID BY ZINC AND MERCURY AMALGAM.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—It may be interesting to some of your readers, more especially those who take an interest in that branch of a medical man's education or curriculum called Chemistry, to know that, although, as is well known, there are many agents which are capable of oxidising sulphuretted hydrogen to sulphuric acid, yet the reverse process, namely, splitting sulphuric acid up into sulphuretted hydrogen and oxygen, was until within the last ten years not thought possible, at least by chemical means, and where it has, only to a very limited extent. The first to publish such observations upon the action of zinc upon the various hydrates of sulphuric acid, were Messrs. Calvert and Johnston, in 1868, and in which they remarked, that though sulphurous acid was chiefly evolved, yet sulphuretted hydrogen was even more so, but less than hydrogen, and according to the same gentlemen, such an acid diluted with six equivalents of water only evolves hydrogen. This, however, was disproved by Kolbe, who showed that even with both acid and zinc quite pure, a small amount of sulphuretted hydrogen was evolved. In most cases, however, where a reduction of sulphuric acid takes place, it stops at sulphurous acid, as when mercury, copper, and carbon act upon the acid.

In an article in an old copy of the *American Chemist*, edited by Dr. Chandler, of New York, it is stated by Dr. Walz, that having studied the action of zinc and sodium amalgam on concentrated sulphuric acid, he finds a considerable amount of sulphuretted hydrogen is formed, and that with this amalgam the action is instantaneous. If a small quantity of sodium amalgam is covered in a test tube with an equal amount of chemically pure sulphuric acid (sp. gr. 1.84) the smell of sulphuretted hydrogen will be at once felt, and on pouring water into the tube it will become milky, with finely divided sulphur held in suspension. However, the reaction is better studied by using zinc instead of the sodium, the action being slower and more regular. The amalgam should be placed in a H₂S apparatus and the gases

passed into a solution of acetate of lead. Hydrogen seems to be first formed, and then sulphuretted hydrogen is given off in abundance. The liquid becomes white, owing to there being a period when sulphurous acid and the sulphuretted hydrogen come off together; the one acting on the other gives rise to this. No mercury enters into solution during the reaction.

Yours, &c.,
N. P. MURRAY.

Edinburgh, January, 1882.

H. D. asks if there is not a method of manufacturing a beverage out of milk somewhat similar to koumiss?

[If ordinary milk be placed in small quantity in a large open stone-ware pan, first mixed with a small quantity of powdered lump sugar, fermentation will rapidly proceed, and the milk will become sour. In twenty-four hours the fermented milk must be put into champagne bottles and well corked down, the cork being fixed with string or wire. On the following day it may be drawn off for use, when it effervesces freely like champagne. Persons with "delicate stomachs," who are unable to take food without nausea, or vomiting, can take with relish the beverage thus produced.—ED.]

PERPLEXED RUSTIC.—"Clubbed" fingers are caused by venous congestion of the parts. It may be variously brought about, and is sometimes produced, as probably in your case, by pressure of an aneurism on the subclavian vein, opposition to the return of the blood from the limb being thereby set up.

"LICHEN."

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—For the past twelve months I have been off and on in attendance on a lady who is suffering from a patch of lichen under and about the outer ankle of her right foot. About six months ago she was almost well, and the pain in the foot had entirely subsided; but from some cause the disease returned, and it is now worse than ever. I have tried arsenic internally and externally. I have tried all I know, and yet the disease continues. The pain in the upper part of the foot and toes is distressing.

If you or any of the readers of the *Medical Press* will be good enough to suggest a remedy, you will much oblige,

Yours faithfully,
A DISPENSARY DOCTOR.

MR. RAINBOW.—You should notify your requirements in our advertising columns; your committee could scarcely hope to get the work done gratuitously.

MR. F. C. C.—There is no prospect whatever of a result happening such as you think possible.

DR. M. C.—Yes, a deputation waited upon the Privy Council last week; the answer is not yet public property.

DR. P.—The death is to be deplored, especially occurring in the manner described; but no blame is attributable to the medical attendants, who were, in fact, not called in until too late. If the public will insist upon employing incompetent midwives, lives that with proper medical assistance would be saved will be constantly sacrificed. Mrs. Gibson undoubtedly did as much as her unskilled knowledge dictated; but Mrs. Gibson should not have been there at all, or if there, should at once have sent for the nearest medical man, and not attempted forcible delivery.

DR. McNAUGHTON JONES.—Letter unavoidably held over for want of space.

MR. G. J. COX (Maidstone).—Your letter well states the practical difficulties encountered in fitting a flue to gas-stoves, but does not affect our statements as to the danger to health. This may possibly be reduced to a minimum in a large well-ventilated hall; but in the first place, even the hall may not be well ventilated; and in the next place, there is always the danger that purchasers, pleased with their heating power, may proceed to fit them in rooms where there is little or no ventilation, *e.g.*, in bedrooms or sitting-rooms without a chimney. You recommend them for offices in your prospectus. The danger of a down-blow can be lessened by taking the fumes into an ordinary chimney-flue where practicable (in preference to taking them direct into the open air), and fitting an exhaust ventilator on the top of the chimney. Where taken direct into the open air the tube should taper outwards and be fitted with some contrivance for preventing draught. The ordinary burner is less likely to be blown out, and is hence safer than the atmospheric burner. As to the lime, the idea was that the products of combustion should pass in a horizontal direction over it—not upwards through a thick layer of it, which, as you say, would not be likely to answer.

MR. W. J. COLLINS.—Letter received as we were at press.

AN OLD BART'S MAN.—See reply to Mr. W. J. Collins.

DR. G. L. B. STONEY.—Proof not returned at time of going to press.

MEETINGS OF THE SOCIETIES.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—This day (Wednesday), at 4 p.m., Prof. W. K. Parker, "On the Morphology of the Mammalian Skull."

HUNTERIAN SOCIETY.—This evening, at 8 o'clock, Address by the President, Dr. Hughlings Jackson.—Dr. Stephen Mackenzie, "On some Cases of Acute Polio-myelitis."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Friday, Feb. 24th, at 4 p.m., Prof. W. K. Parker, "On the Morphology of the Mammalian Skull."

QUERKETT MICROSCOPICAL CLUB.—Friday, Feb. 24th, at 8 p.m., Mr. T. Charters White, "On the Histological Development of the Larva of *Corethra Plumicornis*."

ROYAL INSTITUTION.—Friday, Feb. 24th, at 8 p.m., Prof. Odling, "On Sir B. C. Brodie's Researches on Chemical Allotropy."

CLINICAL SOCIETY OF LONDON.—Friday, Feb. 24th, at 8.30 p.m., Report of the Committee on Dr. Finlay's Case of Aortic Aneurism.—Mr. R. J. Godlee, "On a Case in which a piece of Grass Swallowed by a Child made its exit in an Intercostal Space"—Dr. Geo. Johnson, "On a Case of Sudden Perforative Pneumothorax, with rapid and

complete recovery."—Mr. Spencer Watson, "On a Sequel to a Case of Eyeball Tension, reported in the Clin. Soc. Trans., vol. xiv."—Mr. G. Lawson, "On a Case of Chimney Sweep's Cancer of the Axilla treated by Excision of the Growth, Ligature of Axillary Artery and Amputation of the Arm at Shoulder-joint."—Dr. T. H. Green will show a Case of Subcutaneous Fibroid Nodules in Rheumatism.—Mr. B. Squire will show a Case of Lupus of the Forehead treated by Erasion and Linear Scarification.

SURGICAL SOCIETY OF IRELAND.—Friday, Feb. 24th, at 8.30 p.m.

ROYAL INSTITUTION.—Tuesday, Feb. 28th, at 3 p.m., Prof. Mc Kendrick, "On the Mechanism of the Senses."

Vacancies.

Aberystwyth Infirmary.—House Surgeon. Salary, £175. A knowledge of Welsh desirable. Applications before the 28th inst. (See Advt.)
Belmullet Union, Bangor Dispensary.—Medical Officer. Salary, £100, and £10 as Medical Officer of Health. Election, March 3.
Bushey Sanatorium.—Physician. Full particulars of J. McDonald, Esq., Bushey, Herts. (See Advt.)
Castlebar Union, Castlebar Dispensary.—Medical Officer. Salary, £110, and £15 as Medical Officer of Health. Election, Feb. 25.
Central London Ophthalmic Hospital.—Assistant Surgeon. Honorary. Applications to the Secretary before March 4.
West London Hospital, Hammer-smith.—Assistant Physician. Honorary. Applications to the Secretary before March 1.

Appointments.

ACLAND, T. D., M.B., L.R.C.P., M.R.C.S., Resident Accoucheur to St. Thomas's Hospital, London.
BARTON, J., M.D.T.C.D., M.Ch., F.R.C.S.I., Medical Officer to the South City Dispensary, Dublin.
BUTLER-SMYTH, A. C., M.R.C.S., Honorary Assistant Medical Officer and Chloroformist to the Hospital for Women and Children, Vincent Square, London, S.W.
CARPENTER, A. B., L.R.C.P., M.R.C.S., House Physician to St. Thomas's Hospital, London.
COLLIER, M. P. M., F.R.C.S., M.B. & M.S., House Surgeon to St. Thomas's Hospital, London.
GODSON, C. M.D., M.R.C.P.Lond., Consulting Physician to the City of London Lying-in Hospital.
HAIGBROWN, C. W., M.R.C.S., L.S.A., Assistant House Surgeon to St. Thomas's Hospital, London.
HEELIS, R., M.R.C.S., L.S.A., Junior Assistant House Physician to St. Thomas's Hospital, London.
HERN, W., L.D.S.R.C.S.E., House Surgeon to the Dental Hospital of London.
JACOB, A. H., M.D.T.C.D., F.R.C.S.I., Ophthalmic Surgeon to Richmond Hospital, Dublin.

Births.

ALLEN.—Feb. 15, at Bagenalstown, co. Carlow, the wife of C. D. Allen, M.B., T.C.D., of a son.
GRIMSHAW.—Feb. 13, at Priorsland, Carrickmines, co. Dublin, the wife of Thomas Wrigley Grimshaw, M.D., of a daughter.
RICHARDSON.—Feb. 11, at Lynstead, Torquay, the wife of J. B. Richardson, M.B., of a daughter.
SHERLOCK.—Feb. 14, at 45 Waterloo Road, Dublin, the wife of H. G. Sherlock, F.R.C.S.I., of a son.
SWANZY.—Feb. 15, at 25 Merrion Square, Dublin, the wife of H. B. Swanzy, F.R.C.S.I., of a daughter.
THOMPSON.—Feb. 8, at Wellington Square, Oxford, the wife of Harold Thompson, M.R.C.S., prematurely, of twin girls, who only survived their birth a few hours.
WATSON.—Feb. 16, at Tottenham, Middlesex, the wife of W. Tyndale Watson, M.D., of a son.
WEATHERLY.—Feb. 9, at Portishead, Somerset, the wife of Lionel Alexander Weatherly, M.D., of a daughter.

Deaths.

COWAN.—Feb. 6, suddenly, Alexander Oswald Cowan, M.D., of Church Hill, Edinburgh, aged 47.
MONTFORD.—Feb. 9, at 2 Stanley Villas, Union Mills, Isle of Man, Henry Montford, M.D., aged 66.
PHILIP.—Feb. 3, at Via Della Croce, Rome, Rev. Dr. Philip, M.D., for forty years an able and faithful missionary to the Jews under the British Society for the Propagation of the Gospel.
WHITTELL.—Feb. 8, at his residence, Stewartstown, William Brown Whittell, M.D., aged 85.

FURNISH ON THE NEW HIRE SYSTEM.

(REG.)  (REG.)

Over 40 Wholesale Houses to select Goods from.
List, Prospectus, and Press opinions post free.

The "NEW HIRE SYSTEM" is quite distinct from any other attempted, and has no affinity with the ordinary hiring or "furniture dealers" system. Its great success is due to its equity and to its freedom from undignified surroundings. Houses, Apartments, Offices, &c., can be furnished throughout without increased yearly expenditure; also Hotels, Clubs, &c.—THE GENERAL FURNISHING COMPANY, Offices, 9 SOUTHAMPTON STREET, S'RAND. Est. 1872.

CLINICAL LECTURES ON SYMPTOMS.

Delivered in the Wards of the Hospital.

By FREDERICK T. ROBERTS, M.D., B.Sc., F.R.C.P., Professor of Materia Medica and Therapeutics at University College; Physician and Professor of Clinical Medicine at University College Hospital; Physician to the Brompton Consumption Hospital, &c.

LECTURE VII.—ON THE SYMPTOMATOLOGY OF SYSTEMS AND ORGANS.

HAVING taken a comprehensive survey of symptoms, I desire now to study with you those which are associated with particular organs and structures, in so far as to enable us to understand their nature, and their relations to the several parts. As I have said before, it is not enough merely to know the names of these symptoms, and to be able to enumerate them, but you should endeavour to have an intelligent apprehension of their meaning, and then you will be in a position to appreciate their relations to individual diseases, and also to treat them on true principles. You will understand that I do not intend at present entering into full details about each symptom, but will merely consider them to such an extent as is necessary for our present purpose.

If you will call to mind the classifications of symptoms given in previous lectures, I think you will be prepared to regard them, in relation to systems and organs, according to the following plan:—

1. Ordinary morbid sensations.
2. Peculiar sensations.
3. Local symptoms recognised by objective examination.
4. Functional symptoms.
5. Abnormal actions.
6. Hæmorrhages.
7. Discharges.
8. Symptoms connected with the circulation or blood.
9. Mechanical or physical symptoms.
10. Remote sympathetic or reflex symptoms.
11. General symptoms.

You will observe that in this plan I have merely enumerated the different groups of symptoms of which I have already given a summary, but in a somewhat different way. Now, in studying organs and systems, I propose to point out in regular order what phenomena pertains to each, referable to the several groups, if there should be any. Of course some systems and organs only present symptoms belonging to a limited number, it may be a very few, of these groups, and it is only in exceptional instances that they afford examples of symptoms referable to the whole of them.

It does not matter in what order we take the several parts of the body. We must be guided by the opportunities afforded us of studying them in the wards, according to the cases under our observation; as we have at present several illustrative cases, I propose, therefore, to discuss:—

I.—SYMPTOMS CONNECTED WITH THE CIRCULATORY SYSTEM.

Under this head it will be necessary to deal with—
A. The Heart; B. The Systemic Arteries; C. The Systemic Veins; D. The Pulmonary Vessels.

A.—THE HEART.

Before discussing the nature of the cardiac symptoms, there are certain facts with regard to them which I desire strongly to impress upon you.

First, you must be prepared constantly to meet with cases in which some of these symptoms are present, when there is nothing actually wrong with the heart structurally. In short, this organ is one which is exceedingly liable to "functional" disturbance, from a variety of causes, and, probably, you are familiar with this fact in the frequency with which such symptoms as so-called palpitation, and fainting or syncope occur; and your knowledge of physiology ought to explain the reasons why the heart is subject to so many causes of disturbance.

Secondly, on the contrary, it is a matter of common experience that organic disease of the heart exists, even of a serious character, so serious that it may cause sudden death, and yet no symptoms whatever are present, the

mischief being only detected by physical examination. We have some striking cases illustrative of this statement under our observation at the present time.

Thirdly, when symptoms are present in cases of organic cardiac lesions, it is always extremely important to study them in relation to the signs elicited by physical examination. They give much information as to the way in which the heart is working, as to the condition of the circulation, and other points which mere physical examination cannot reveal. Also, you must be prepared for the occurrence of slight symptoms, clearly dependent upon the heart, and indicating organic changes in its substance, which you cannot discover by physical signs. These symptoms I will point out to you hereafter.

Fourthly, as you will see more clearly when we come to study the nature of cardiac symptoms, you must understand, at the outset, that the most important of these symptoms are to be found, not in immediate connection with the heart itself, but throughout the body generally, or in various parts of it, or associated with certain organs. This you will readily comprehend if you bear in mind that they are mainly produced through some disturbance of the blood-circulation, to carry on which is the function of the heart. Moreover, such symptoms are liable, in many cases, to become more or less independent of the direct influence of the heart in course of time, inasmuch as the disordered circulation tends to set up permanent organic changes in the various structures and organs of the body.

Fifthly, you must be very cautious in giving your opinion as regards the immediate prognosis of cardiac complaints from the symptoms present; and also never forget the remarkable effect which can often be produced upon the most serious of them by treatment. Very slight symptoms may mean grave danger, and may most unexpectedly precede a fatal termination; while those which are apparently hopeless not unfrequently disappear under suitable therapeutic measures, and the patient seems to be restored to complete health. We have cases in these wards at the present time which have been here on more than one occasion, suffering from more severe symptoms than they exhibit now, and they have so much benefited by treatment that we have been able to discharge them for the time, apparently free from all symptoms.

After these preliminary remarks, we will now proceed to consider the nature of cardiac symptoms.

1. ORDINARY MORBID SENSATIONS.—Painful sensations have to be regarded with particular caution in relation to affections of the heart, both from a positive and a negative point of view. Patients frequently complain of pain in the left side, which they associate with the heart; but you ought not to be led away by their notions, or by what they say. As a matter of fact, such pains are seldom connected with the heart, but with the chest-walls, the pleura, the stomach, or other structures; while the majority of cases of actual cardiac disease are not attended with any ordinary painful sensation whatever. Even in acute affections, where we expect pain, you must be prepared at any time to meet with instances where no such feeling is complained of or experienced. In short, taking the mass of cases, it may be affirmed that pain is, as a rule, a very unreliable symptom, either as to the presence or absence of cardiac diseases. At the same time you must be prepared to recognise the kinds of pain which may come under your observation, and which are, in some instances, of great significance. The most important are as follows:—

a. We anticipate and look for pain in *acute inflammatory diseases* associated with the heart. Therefore, if any condition exists in which such inflammation might be expected, and especially acute rheumatism or Bright's disease, the slightest complaint of any abnormal sensation referred to the cardiac region ought to command your immediate attention. But if you were to wait, under such circumstances, until the patient complains, you would commit a grave error, for serious lesions would frequently be set up of which you would be entirely ignorant, and which can only, though very readily, be recognised by

physical examination. Hence, you know we make it a rule to examine the heart in every case of acute or sub-acute rheumatism once, twice, or even more frequently, every day, without any reference to the presence or absence of symptoms. This is the only plan that can save you from overlooking important acute cardiac affections. What I have just stated applies with peculiar force to cases of inflammation involving the endocardium and valves, or the substance of the heart itself. In pericarditis we much more frequently meet with pain, of some degree or other. With regard to the particular features of the pain which may attend acute cardiac inflammation, I can only say that it is usually referred to the præcordial region generally, or more commonly to some limited area of this region, though occasionally it is chiefly felt towards the epigastrium; that it, however, tends to shoot and stab in different directions; that it varies much in its intensity, from slight discomfort or uneasiness to the most severe suffering; that its character also differs, but is not uncommonly burning in pericarditis; and that it is aggravated, sometimes considerably, by pressure made over the cardiac region or, in some instances, upwards from the epigastrium, tenderness being indeed occasionally present when no spontaneous pain is complained of.

b. There are certain paroxysms of a painful nature associated with the heart, which are usually very characteristic, and which are expressed by the term *angina pectoris*. These supervene, as a rule, in cases of well-recognised cardiac disease, but they may occur where the heart is affected so slightly that this cannot be determined by physical examination, or even where the organ is quite healthy to all appearance. We have had two striking examples of attacks of this character in the wards during the present session, in both of which the aortic orifice and valves and the aorta itself were diseased; and in my experience these are the lesions in connection with which *angina pectoris* is ordinarily observed. Whenever attacks of this kind occur, and more particularly when any cardiac affection is known to exist, they should receive immediate and serious attention. Without going into full details, it will suffice to state that *angina pectoris* is characterised by paroxysms of pain, usually coming on with marked suddenness; of great intensity, and sometimes unbearable; commencing in some part of the cardiac region, but, as a rule, shooting in different directions, and even down the left arm, or occasionally the right; varying much in character; generally accompanied with a marked sense of oppression, constriction, or compression of the chest, and of impending suffocation, the breathing being checked; and relieved by pressure. More or less serious symptoms accompany an attack, and not uncommonly it terminates fatally. In favourable cases the pain usually subsides more or less suddenly, and the patient experiences great relief, but another paroxysm is liable to return. It is remarkably influenced by certain remedies, and especially by inhalations of nitrite of amyl. I cannot now enter into a discussion of the pathology of *angina pectoris*, but it may be affirmed that it immediately arises from some serious disturbance affecting the cardiac muscular walls, supposed by some authorities to be of the nature of spasm, by others of paralysis and consequent distension of the heart.

c. It will be sufficient to mention the sudden and terrible pain which may attend *rupture* of the heart.

d. Taking the mass of cases of *chronic* cardiac disease, they are remarkably free from any persistent painful sensation, and it is quite the exception for patients to complain in these cases of any such sensation. In some instances more or less pain or uneasiness may be experienced in the præcordial region from time to time, but, as a rule, it has no special significance. It is said that pain is more frequently felt in aortic disease than in other forms of cardiac mischief, and perhaps there is some truth in this statement. Some of the most conspicuous examples of chronic pain referred to the heart which I have met with, have been those in which there were marked pericardial adhesions. I have now and then

observed instances in which the sensation seemed to be due to the presence of a greatly enlarged heart, distending or irritating the structures forming the chest-walls; and it has been relieved by supporting the side by means of plaster or a bandage. The chronic painful sensations in cardiac diseases are rarely severe, even when present, and often amount only to slight discomfort and annoyance. Remember, then, that such sensations in the left side are, practically, of no importance, either as regards the positive or negative diagnosis of diseases of the heart, although, of course, if a patient complained of them, you should examine the heart as well as other structures.

2. PECULIAR SENSATIONS.—The heart is one of the organs associated with which we have to recognise certain special local sensations, which are not uncommonly of much significance.

a. In the first place the patient is usually conscious of any abnormal action of the heart, and expresses this by complaining of *palpitation*. The sensations will vary with the nature of the disturbed action, and do not merely consist in feelings of excessive force and rapidity, as the word *palpitation* is often supposed to imply. Indeed, the patient may thus recognise feeble or inefficient cardiac force, as well as irregularity or intermittence, and may express himself by saying that "he feels as if his heart were going to stop." The precise sensations are, therefore, variable, and may be indescribable. Amongst the most familiar may be mentioned those of rolling of the heart, jogging, falling back, or as if the organ were suddenly "jumping into the throat." They may be merely unpleasant and uncomfortable; or they are attended with various degrees of distress and anxiety, until they culminate in the most extreme dread of impending death, accompanied with horrible feelings. These sensations are sometimes designated by the term "*præcordial anxiety or distress*." They are not only met with in organic diseases, but also in a very severe form sometimes in mere functional disorders. They often become very troublesome just as the patient is dropping off to sleep, and thus become a source of danger through interfering with sleep. They are also frequently increased by lying with the head too low, or on the left side. Towards the fatal close of certain cases of cardiac disease, these feelings become exceedingly troublesome to deal with. On the other hand, it is worthy of remark that patients sometimes become so accustomed gradually to various forms of disturbed cardiac action, that they cease to notice, and are not conscious of them, even when they are very marked.

b. Another peculiar feeling not uncommonly experienced in connection with the heart is that of weight, fulness, or oppression over the cardiac region, or even across the chest—*præcordial oppression*. This may be combined with pain or other sensations already described, and it may become so aggravated that the patient feels as if his chest were tightly gripped, and he cannot overcome the resistance so as to expand it. In some instances there is a sensation of an opposite character, as if there were a want of something, a hollowness, or sinking in the cardiac region. Frequently it is difficult to explain these feelings, but those of oppression and fulness may depend upon actual objective conditions, such as pericardial effusion, or a greatly enlarged heart.

c. Although belonging to another system, it is proper to allude to the feelings associated with *respiration* which are so commonly noticed in cardiac affection. The sense of difficulty in expanding the chest has already been referred to. There are, in addition, the sensations accompanying the different forms of dyspnoea met with in these affections; and certain special feelings occasionally observed, such as a tendency to involuntary sighing, or to drawing a full and deep breath.

(To be continued.)

THE CAUSES, SYMPTOMS, AND TREATMENT OF TETANUS.

A Clinical Lecture delivered in the Meath Hospital and co. Dublin Infirmary.

By LAMBERT H. ORMSBY, F.R.C.S.,
Lecturer on Clinical and Operative Surgery.

GENTLEMEN,—I shall occupy your attention this morning for a short time by giving you a brief account of the disease called Tetanus, and before doing so I shall read you the following notes of a case that occurred in this hospital, taken from the "Hospital Case-book," in order to give you a slight idea of the commencement, course, and termination this desperate disease invariably takes.

Patrick H., æt. 15, living at Whitehall, near Crumlin, co. Dublin, came to the Meath Hospital on February 15th, 1879, with a very severe lacerated wound between the thumb and index finger of his left hand.

State on admission.—The metacarpo-phalangeal articulation was exposed, and several pieces of muscle and tendon were hanging out of the wound dead and blackened. These were removed, the wound closed, and the edges brought into position and secured by three points of suture. There was scarcely any hæmorrhage. The wound looked so well that the boy said he would go home and come in a few days to be dressed.

Cause of Injury.—The account he gave was that he had been amusing himself by pouring gunpowder out of a flask on the fire, when the contents ignited, blowing the flask out of his hand. Luckily, the flask did not burst till it had gone some distance out of his hand.

Redressed on the 17th February, when he came again to show his hand, and as there was considerable suppuration, he was ordered to poultice it.

On the 20th February, he was brought again, presenting the following premonitory *symptoms* of tetanus: The back was arched; head thrown back and fixed immovably to the shoulder; chin advanced and elevated; corners of the mouth drawn up, showing the teeth, presenting a good example of the *sardonic grin*; eyes peering, as if short-sighted; eyelids depressed, and brows contracted; jaws opened half-an-inch, and incapable of being opened more; and the masseter muscles were hard and rigid.

Treatment adopted.—The surgeon on duty was immediately sent for, and while waiting his arrival, Mr. Lingard, the resident pupil, ordered the patient to be put to bed with a warm jar to his feet. The wound was washed, and wet lint applied, and a purgative draught administered containing 1 minim of croton oil, 12 minims of liquoris morphie muriatis; and 2 minims of liquor atropie were injected subcutaneously along the spine between the scapulae. This subcutaneous injection was ordered to be repeated every four or five hours. He was also given three grains of calomel, to be repeated every three hours, and a linseed-meal poultice, saturated with liq. opii sed. to be applied to the part affected; the room to be darkened, and the floor to be carpeted, and no noise of any kind to be allowed within earshot of the patient. The boy was admitted at 5.30 p.m. At 7 p.m. the back was more curved, and the jaws could hardly be opened at all.

9 p.m.—Another hypodermic injection and dose of calomel administered.

11 p.m.—The severity of the symptoms increased; had the second spasm since he came in, and bit his tongue; it lasted only a few seconds. A cork was then introduced between his teeth.

12 p.m.—Another spasm, and his body was very much bowed backwards. *Opisthotonos*. When in the middle of the spasm, his body rested on the occiput and on the heels; during this spasm he bit his tongue again; he said that the spasm came on everytime he went to sleep;

mischiefs being only detected by physical examination. We have some striking cases illustrative of this statement under our observation at the present time.

Thirdly, when symptoms are present in cases of organic cardiac lesions, it is always extremely important to study them in relation to the signs elicited by physical examination. They give much information as to the way in which the heart is working, as to the condition of the circulation, and other points which mere physical examination cannot reveal. Also, you must be prepared for the occurrence of slight symptoms, clearly dependent upon the heart, and indicating organic changes in its substance, which you cannot discover by physical signs. These symptoms I will point out to you hereafter.

Fourthly, as you will see more clearly when we come to study the nature of cardiac symptoms, you must understand, at the outset, that the most important of these symptoms are to be found, not in immediate connection with the heart itself, but throughout the body generally, or in various parts of it, or associated with certain organs. This you will readily comprehend if you bear in mind that they are mainly produced through some disturbance of the blood-circulation, to carry on which is the function of the heart. Moreover, such symptoms are liable, in many cases, to become more or less independent of the direct influence of the heart in course of time, inasmuch as the disordered circulation tends to set up permanent organic changes in the various structures and organs of the body.

Fifthly, you must be very cautious in giving your opinion as regards the immediate prognosis of cardiac complaints from the symptoms present; and also never forget the remarkable effect which can often be produced upon the most serious of them by treatment. Very slight symptoms may mean grave danger, and may most unexpectedly precede a fatal termination; while those which are apparently hopeless not infrequently disappear under suitable therapeutic measures, and the patient seems to be restored to complete health. We have cases in these wards at the present time which have been here on more than one occasion, suffering from more severe symptoms than they exhibit now, and they have so much benefited by treatment that we have been able to discharge them for the time, apparently free from all symptoms.

After these preliminary remarks, we will now proceed to consider the nature of cardiac symptoms.

1. ORDINARY MORBID SENSATIONS.—Painful sensations have to be regarded with particular caution in relation to affections of the heart, both from a positive and a negative point of view. Patients frequently complain of pain in the left side, which they associate with the heart; but you ought not to be led away by their notions, or by what they say. As a matter of fact, such pains are seldom connected with the heart, but with the chest-walls, the pleura, the stomach, or other structures; while the majority of cases of actual cardiac disease are not attended with any ordinary painful sensation whatever. Even in acute affections, where we expect pain, you must be prepared at any time to meet with instances where no such feeling is complained of or experienced. In short, taking the mass of cases, it may be affirmed that pain is, as a rule, a very unreliable symptom, either as to the presence or absence of cardiac diseases. At the same time you must be prepared to recognise the kinds of pain which may come under your observation, and which are, in some instances, of great significance. The most important are as follows:—

a. We anticipate and look for pain in *acute inflammatory diseases* associated with the heart. Therefore, if any condition exists in which such inflammation might be expected, and especially acute rheumatism or Bright's disease, the slightest complaint of any abnormal sensation referred to the cardiac region ought to command your immediate attention. But if you were to wait, under such circumstances, until the patient complains, you would commit a grave error, for serious lesions would frequently be set up of which you would be entirely ignorant, and which can only, though very readily, be recognised by

physical examination. Hence, you know we make it a rule to examine the heart in every case of acute or sub-acute rheumatism once, twice, or even more frequently, every day, without any reference to the presence or absence of symptoms. This is the only plan that can save you from overlooking important acute cardiac affections. What I have just stated applies with peculiar force to cases of inflammation involving the endocardium and valves, or the substance of the heart itself. In pericarditis we much more frequently meet with pain, of some degree or other. With regard to the particular features of the pain which may attend acute cardiac inflammation, I can only say that it is usually referred to the præcordial region generally, or more commonly to some limited area of this region, though occasionally it is chiefly felt towards the epigastrium; that it, however, tends to shoot and stab in different directions; that it varies much in its intensity, from slight discomfort or uneasiness to the most severe suffering; that its character also differs, but is not uncommonly burning in pericarditis; and that it is aggravated, sometimes considerably, by pressure made over the cardiac region or, in some instances, upwards from the epigastrium, tenderness being indeed occasionally present when no spontaneous pain is complained of.

b. There are certain paroxysms of a painful nature associated with the heart, which are usually very characteristic, and which are expressed by the term *angina pectoris*. These supervene, as a rule, in cases of well-recognised cardiac disease, but they may occur where the heart is affected so slightly that this cannot be determined by physical examination, or even where the organ is quite healthy to all appearance. We have had two striking examples of attacks of this character in the wards during the present session, in both of which the aortic orifice and valves and the aorta itself were diseased; and in my experience these are the lesions in connection with which *angina pectoris* is ordinarily observed. Whenever attacks of this kind occur, and more particularly when any cardiac affection is known to exist, they should receive immediate and serious attention. Without going into full details, it will suffice to state that *angina pectoris* is characterised by paroxysms of pain, usually coming on with marked suddenness; of great intensity, and sometimes unbearable; commencing in some part of the cardiac region, but, as a rule, shooting in different directions, and even down the left arm, or occasionally the right; varying much in character; generally accompanied with a marked sense of oppression, constriction, or compression of the chest, and of impending suffocation, the breathing being checked; and relieved by pressure. More or less serious symptoms accompany an attack, and not uncommonly it terminates fatally. In favourable cases the pain usually subsides more or less suddenly, and the patient experiences great relief, but another paroxysm is liable to return. It is remarkably influenced by certain remedies, and especially by inhalations of nitrite of amyl. I cannot now enter into a discussion of the pathology of *angina pectoris*, but it may be affirmed that it immediately arises from some serious disturbance affecting the cardiac muscular walls, supposed by some authorities to be of the nature of spasm, by others of paralysis and consequent distension of the heart.

c. It will be sufficient to mention the sudden and terrible pain which may attend *rupture* of the heart.

d. Taking the mass of cases of *chronic* cardiac disease, they are remarkably free from any persistent painful sensation, and it is quite the exception for patients to complain in these cases of any such sensation. In some instances more or less pain or uneasiness may be experienced in the præcordial region from time to time, but, as a rule, it has no special significance. It is said that pain is more frequently felt in aortic disease than in other forms of cardiac mischief, and perhaps there is some truth in this statement. Some of the most conspicuous examples of chronic pain referred to the heart which I have met with, have been those in which there were marked pericardial adhesions. I have now and then

observed instances in which the sensation seemed to be due to the presence of a greatly enlarged heart, distending or irritating the structures forming the chest-walls; and it has been relieved by supporting the side by means of plaster or a bandage. The chronic painful sensations in cardiac diseases are rarely severe, even when present, and often amount only to slight discomfort and annoyance. Remember, then, that such sensations in the left side are, practically, of no importance, either as regards the positive or negative diagnosis of diseases of the heart, although, of course, if a patient complained of them, you should examine the heart as well as other structures.

2. PECULIAR SENSATIONS.—The heart is one of the organs associated with which we have to recognise certain special local sensations, which are not uncommonly of much significance.

a. In the first place the patient is usually conscious of any abnormal action of the heart, and expresses this by complaining of *palpitation*. The sensations will vary with the nature of the disturbed action, and do not merely consist in feelings of excessive force and rapidity, as the word *palpitation* is often supposed to imply. Indeed, the patient may thus recognise feeble or inefficient cardiac force, as well as irregularity or intermittence, and may express himself by saying that "he feels as if his heart were going to stop." The precise sensations are, therefore, variable, and may be indescribable. Amongst the most familiar may be mentioned those of rolling of the heart, jogging, falling back, or as if the organ were suddenly "jumping into the throat." They may be merely unpleasant and uncomfortable; or they are attended with various degrees of distress and anxiety, until they culminate in the most extreme dread of impending death, accompanied with horrible feelings. These sensations are sometimes designated by the term "*præcordial anxiety or distress*." They are not only met with in organic diseases, but also in a very severe form sometimes in mere functional disorders. They often become very troublesome just as the patient is dropping off to sleep, and thus become a source of danger through interfering with sleep. They are also frequently increased by lying with the head too low, or on the left side. Towards the fatal close of certain cases of cardiac disease, these feelings become exceedingly troublesome to deal with. On the other hand, it is worthy of remark that patients sometimes become so accustomed gradually to various forms of disturbed cardiac action, that they cease to notice, and are not conscious of them, even when they are very marked.

b. Another peculiar feeling not uncommonly experienced in connection with the heart is that of weight, fulness, or oppression over the cardiac region, or even across the chest—*præcordial oppression*. This may be combined with pain or other sensations already described, and it may become so aggravated that the patient feels as if his chest were tightly gripped, and he cannot overcome the resistance so as to expand it. In some instances there is a sensation of an opposite character, as if there were a want of something, a hollowness, or sinking in the cardiac region. Frequently it is difficult to explain these feelings, but those of oppression and fulness may depend upon actual objective conditions, such as pericardial effusion, or a greatly enlarged heart.

c. Although belonging to another system, it is proper to allude to the feelings associated with *respiration* which are so commonly noticed in cardiac affections. The sense of difficulty in expanding the chest has already been referred to. There are, in addition, the sensations accompanying the different forms of dyspnoea met with in these affections; and certain special feelings occasionally observed, such as a tendency to involuntary sighing, or to drawing a full and deep breath.

(To be continued.)

THE CAUSES, SYMPTOMS, AND TREATMENT OF TETANUS.

A Clinical Lecture delivered in the Meath Hospital and co. Dublin Infirmary.

By LAMBERT H. ORMSBY, F.R.C.S.,

Lecturer on Clinical and Operative Surgery.

GENTLEMEN,—I shall occupy your attention this morning for a short time by giving you a brief account of the disease called Tetanus, and before doing so I shall read you the following notes of a case that occurred in this hospital, taken from the "Hospital Case-book," in order to give you a slight idea of the commencement, course, and termination this desperate disease invariably takes.

Patrick H., æt. 15, living at Whitehall, near Crumlin, co. Dublin, came to the Meath Hospital on February 15th, 1879, with a very severe lacerated wound between the thumb and index finger of his left hand.

State on admission.—The metacarpo-phalangeal articulation was exposed, and several pieces of muscle and tendon were hanging out of the wound dead and blackened. These were removed, the wound closed, and the edges brought into position and secured by three points of suture. There was scarcely any hæmorrhage. The wound looked so well that the boy said he would go home and come in a few days to be dressed.

Cause of Injury.—The account he gave was that he had been amusing himself by pouring gunpowder out of a flask on the fire, when the contents ignited, blowing the flask out of his hand. Luckily, the flask did not burst till it had gone some distance out of his hand.

Redressed on the 17th February, when he came again to show his hand, and as there was considerable suppuration, he was ordered to poultice it.

On the 20th February, he was brought again, presenting the following premonitory symptoms of tetanus: The back was arched; head thrown back and fixed immovably to the shoulder; chin advanced and elevated; corners of the mouth drawn up, showing the teeth, presenting a good example of the *sardonic grin*; eyes peering, as if short-sighted; eyelids depressed, and brows contracted; jaws opened half-an-inch, and incapable of being opened more; and the masseter muscles were hard and rigid.

Treatment adopted.—The surgeon on duty was immediately sent for, and while waiting his arrival, Mr. Lingard, the resident pupil, ordered the patient to be put to bed with a warm jar to his feet. The wound was washed, and wet lint applied, and a purgative draught administered containing 1 minim of croton oil, 12 minims of liquoris morphie muriatis; and 2 minims of liquor atropiæ were injected subcutaneously along the spine between the scapula. This subcutaneous injection was ordered to be repeated every four or five hours. He was also given three grains of calomel, to be repeated every three hours, and a linseed-meal poultice, saturated with liq. opii sed. to be applied to the part affected; the room to be darkened, and the floor to be carpeted, and no noise of any kind to be allowed within earshot of the patient. The boy was admitted at 5.30 p.m. At 7 p.m. the back was more curved, and the jaws could hardly be opened at all.

9 p.m.—Another hypodermic injection and dose of calomel administered.

11 p.m.—The severity of the symptoms increased; had the second spasm since he came in, and bit his tongue; it lasted only a few seconds. A cork was then introduced between his teeth.

12 p.m.—Another spasm, and his body was very much bowed backwards. *Opisthotonos*. When in the middle of the spasm, his body rested on the occiput and on the heels; during this spasm he bit his tongue again; he said that the spasm came on everytime he went to sleep;

the muscles of the jaw, producing trismus very early in the disease, afterwards passing to the muscles of the extremities, whereas the reverse is the fact in strychnia poisoning, the legs and arms being the first affected, long before trismus ensues, and this locking of the jaw is only present during the attack, being relaxed in the interval; whereas in true tetanus trismus is constant. If the effects of strychnia prove fatal, it generally does so from a few minutes to within three hours; whereas in true tetanus death generally does not take place sooner than the third or fourth day, and frequently later.

Hysterical attacks also simulate tetanus as well as almost any other disease. Hammond relates a case of a lady under his care who had repeated attacks of hysterical spasms, during which her jaws were tightly closed, she was unable to swallow, and her body was bent backwards, so as to assume the position of opisthotonos.

Such hysterical seizures are readily distinguished from tetanus by the facts that they are unaccompanied by pain or real distress, and are as a rule of a very transient nature, and other hysterical symptoms are generally present, and by the history of the case, coupled with careful observation; inquiry will seldom fail to elicit the true nature of the affection.

Prognosis.—In cases of acute traumatic tetanus the prognosis is most unfavourable. In the idiopathic or chronic form of the disease a more hopeful result may as a rule be entertained, but still it ought to be guarded. If the time between the receipt of the injury and the setting in of the premonitory symptoms is considerable, the chances are in favour of the patient recovering. If the attacks are very slight, and the intervals between the muscular spasms are long, with a low bodily temperature, such a condition indicates that it is probable the case may recover. A high temperature augurs badly for the patient.

The longer the person lives the better chance there is of recovery. If ten days pass over without a fatal result a favourable termination may be hoped for, although this expectation cannot be considered by any means as a certainty, for patients have died suddenly after the disease has existed for many weeks.

Notwithstanding what has been said, tetanus is certainly one of the most fatal of disorders, and we have only to appeal to a few statistics to verify the truth of this observation.

In the late American civil war, out of 363 cases of tetanus, 336 died. Dr. O'Beirne, as mentioned in the "Dublin Hospital Reports," vol. iii., pp. 343, 378, gives 200 cases without a single recovery. Heunen, with his extended experience in military practice, never saw a case of acute tetanus recover. McCleod collected and analysed 23 cases which occurred among the troops in the Crimean war, of which but 2 recovered. Demme refers to 86 cases in the different Italian hospitals during the campaign of 1859, of which only 6 recovered. Hammond mentions he had 9 cases under his care, of which there were 3 recoveries.

Now by the foregoing it will be clearly seen that a most unpromising result only too often crowns the labours of the surgeon who endeavours to save a human life or mitigate the sufferings of the patient who is stricken down with this most dreadful disorder.

Notwithstanding, however, that the disease is so fatal, and treatment in some cases of so little avail, it is the duty of the surgeon to combat the disease to the very last by treating each symptom as it arises, and continuing to do so until a favourable or unfavourable termination puts an end to the patient's sufferings.

(To be continued.)

THE ADMINISTRATION AND HYGIENE OF BRITISH HOSPITALS. (a)

By HENRY C. BURDETT, F.S.S.

So much misapprehension prevails as to the origin of hospitals, that it seems desirable to show by actual evidence that they were known previous to the birth of Christ. The inhabitants of Arabia, Persia, and India, possessed hospitals, some of which were supported by their governments long before the Christian Era. The Buddhists cut on rocks their edicts on hospitals, one of which, dated a.c. 220, can be seen near Sourat to this day. Medicines were provided, and skilled physicians were appointed to these hospitals at the expense of the State. All the physicians attached to the court, male and female, were compelled to give their services gratuitously to each of the hospitals as they might be required. Hospitals were established amongst the fire worshippers of Persia from the earliest times, the people being compelled by law to maintain suitable houses for the suffering poor of their community, whilst the king provided the best medical treatment for the inmates, free of cost. It is declared, upon evidence not entirely unauthenticated, that the sick were treated so far back as 1,124 B.C. in the temples of Æsculapius, at Titanus, a city of Peloponnesus. The Æsculapian temples had some features, at any rate, in common with our hospitals. Certain of these buildings were set aside for the exclusive treatment of patients suffering from infectious diseases. Tablets were suspended upon the walls, on which were recorded the history and treatment of each patient.

Finally, the Valetudinarius referred to by Seneca and others were in reality private pay hospitals or hydropathic establishments for the well-to-do. The first Christian hospital was founded at Bethlehem by St. Jerome in the year A.D. 300, and he it was who first used the word "Hospital" to describe an institution devoted exclusively to the reception and relief of the sick. St. Ephraim or St. Faviola is entitled to the credit of founding infirmaries, which were supported exclusively by voluntary contributions, and for the sole purpose of treating the sick.

The oldest Hospital in Europe now in use is the Hôtel-Dieu, which was founded A.D. 600 by St. Landry, Bishop of Paris; and the first hospital opened in England was built at Canterbury by Archbishop Lanfranc. Mr. Burdett pointed out as a remarkable fact, that Guy's Hospital, which is one of a very few, if not the only English hospital founded on the monumental, as opposed to the Christian idea, has recently been the scene of serious controversy, which report declares to be due, at the bottom, to differences of opinion on religious matters.

This circumstance is noteworthy as showing that money left for a specific purpose by a benevolent founder may, in process of time, come under the absolute control of those whose views, and whose mode of administration, are probably very little in accord with the views and intentions of the originator himself.

Passing from the past to the present, Mr. Burdett showed that the number of beds available in the General, Special, and Convalescent Institutions throughout Great Britain approached 25,000, exclusive of Poor-law and Cottage hospitals. The number of patients relieved every year at some 200 institutions was nearly 190,000; the number of out-patients relieved at 250 General and Special Hospitals, and Provident and General Dispensaries, was nearly 2,000,000 annually. The average gross annual income from all sources received by British Hospitals, Convalescent Institutions, and Dispensaries amounts to £1,450,452, and the average gross annual expenditure to £1,447,601. These figures, which are based upon the average receipts, expenditure, and work during three years, prepared upon an identical basis, and checked by an accountant, went to prove that if the incomes of the

(a) Abstract of a paper read before the Sanitary Institute of Great Britain, Wednesday, February 15th, 1882.

different medical charities were fairly distributed according to the requirements of each centre of population, the funds available would be equal to the demand.

As a matter of fact, many of the leading London hospitals are now very seriously embarrassed from want of funds. No less than three of the chief of them—St. George's, King's College, and Westminster—have, within the last few days, brought their impecuniosity prominently before the public in the columns of the *Times*. In a leading article which these appeals called forth, the *Times*, alluding to a deputation of two years ago to the Home Secretary, which urged upon him the necessity of appointing a Royal Commission to inquire into the whole subject, and to his reply "that public opinion was not yet ripe for such an inquiry," remarked: "It seems likely that the condition of ripeness, if not absolutely reached, is at least brought within a measurable distance of time." An inquiry can do no possible harm. By its means alone can the exact facts be ascertained, and the sooner a Royal Commission is appointed the better it will be for the hospitals, the public, and the poor.

Mr. Burdett then proceeded to consider the best scheme upon which British hospitals can be governed and managed. He pointed out the abuses attending the acceptance, without the fullest inquiry, of the offices of President, or Vice-President of a charity by a member of the Royal Family, a Bishop of the Church, a Peer of the Realm, or other representative personages. The name once given, the promoters were enabled to use it as a kind of peg upon which to hang any number of appeals for support, and any number of schemes for bleeding the charitable public. No name ought to be given to any charity without the most careful, thorough and competent inquiry. Mr. Burdett further pointed out the evils attending the present system of selecting any apparently presentable person who might offer himself for the office of superintendent or secretary to a hospital. There could be no doubt that to elect a half-pay officer, with a small pension, to such an office, because it enabled the Committee to pay something less than a fair rate of remuneration for the services of a gentleman in such a position, was to do great mischief to the charity, and great wrong to the individual. The labourer is worthy of his hire, and it would be a wise step for Hospital Committees to decide to pay such a rate of remuneration as would enable them to command the services of the most eligible candidates, especially as such a result could be obtained if the maximum salary of such an official were fixed at 5 per cent. upon the annual income of each hospital. Mr. Burdett showed it would be possible to train men for these positions to the great advantage of the Institutions, and to the great economy of charitable funds.

He referred to the dangers of non-formula prescribing in out-patient rooms, by which system overworked dispensers became the unwitting means of causing serious risks to the health and sometimes to the lives of those of Her Majesty's subjects who seek this kind of relief at the hospitals. The ticket system was criticised unfavourably, while the free system was extolled, the advantages and disadvantages in each case being fully stated. Allusion was made to a proposal now in course of adoption, to establish a North Metropolitan Hospital for North London, with 300 beds, upon the most approved principles of hospital administration known to those best competent to form an opinion on the subject. It was also declared to be desirable for inquiry to be made into the present system of managing British hospitals, and for a Hospital Society to be formed with the object of effecting a free interchange of views between hospital authorities.

On the question of hygiene Mr. Burdett showed, by quoting instances, that in the majority of cases the hospital committees have imperfect plans or none at all of the drainage of such institutions, and are often in entire ignorance of many points relating thereto which ought to be as familiar to them as the letters of the alphabet. The relative mortality of large and small

hospitals, the right system of drainage, the advantages of isolated wards adjoining the operating theatre for the treatment of such cases, and the best system of managing infectious and convalescent hospitals with a due regard for the public health, were fully dealt with.

In conclusion, Mr. Burdett expressed his opinion, based as it was on actual experience, and many years' study of the subject, that Hospital Saturday had practically proved a failure everywhere. In London, Hospital Saturday more nearly resembled a fiasco than a failure, for after several years' labour, begging for alms in the public streets, the institution of numerous benefit performances, and other means which the working men justly regarded as illegitimate, the sum subscribed by the whole of the working men in London for upwards of 100 hospitals and other institutions amounted to a less sum than the workmen in the Clyde have frequently subscribed for one of the hospitals at Glasgow. The proposal to institute a Convalescent Institution, which should be founded and supported by the working classes in the metropolis, was worthy of commendation. He hoped that it would result in the abandonment of the Hospital Saturday movement, in favour of a working men's provident Convalescent Home. Such a result would relieve the London hospitals from much anxiety, and would get rid of a movement which, in his opinion, did the hospitals far more harm than good, and which had never proved, and was never likely to prove, a substantial financial success.

Clinical Records.

Huddersfield Infirmary.

A Case in which there was Dislocation of both Knees.

Under the care of Mr. RHODES.

(Reported by Mr. NORMAN PORRITT, House Surgeon.)

THE following case is recorded on account of the rarity of the injury:—

The patient, a strong muscular man, *et. 31*, was, contrary to orders, attempting to put a strap on a rapidly revolving drum, when the apron he wore in front of him flapped against the machinery, became at once entangled, and he was carried round the shaft or axle of the drum with each revolution. The shaft was not more than two feet from the floor, against which, therefore, the man was dashed many times before the machinery could be stopped. When this was done he was found unconscious, and his clothes were torn from his body, and lay in shreds about.

He was at once conveyed to this Infirmary, where, besides bruising of the whole body, several scalp wounds, and severe shock to the system, a deformity of the legs at first sight resembling that caused by the prominence of a fragment of a broken femur was discovered. There was considerable restlessness, and the man raised both legs in his paroxysms, without any alteration of the deformity. On handling the limb at the injured spot, the tendon of the quadriceps extensor was loose, and behind the patella was a hollow cavity, produced by the displacement of the lower end of the femur behind the head of the tibia. By very slight force and manipulation the normal position of the bones was restored, but without any difficulty the joint could be re-dislocated, the femur being as easily pushed behind the tibia, on the one hand, as the tibia could be made to pass above and behind the condyles of the femur, on the other.

The patient never recovered consciousness, and died in thirty-six hours. No post-mortem allowed. In both knees there was the same displacement, without any fracture.

WOMAN'S HOSPITAL, NEW YORK.

Removal of a Cyst of the Pancreas weighing Twenty and One-half Pounds.

Under the care of Dr. N. BOZEMAN.

DR. BOZEMAN has kindly forwarded us particulars of this interesting case, which was presented at a recent meeting

of the New York Pathological Society. The following is its history, the points of interest being—firstly, as having been removed from the pancreas of a living woman; secondly, as having been mistaken for an ovarian cyst; and thirdly, as being the first operation of the kind upon record.

The patient was the wife of a prominent physician of Texas, *æt.* 41, tall and robust, weighing nearly 200 pounds, and perfectly healthy up to seven years ago, except occasional attacks of dyspepsia. Seven years ago she had, for the first time, pain in the right iliac region, extending down the right thigh and occasionally attended with numbness. Five years ago the abdomen began to enlarge, slowly at first, but gradually increased in size upon the left side, with a corresponding flatness upon the right side. The point at which the enlargement was first noticed was higher than would naturally be expected for an ovarian cyst. At that time no special importance was attached to the enlargement of the abdomen, either by herself or husband. It progressed in the ordinary way up to six or seven months ago, when it suddenly began to grow rapidly, and finally the entire abdomen was distended symmetrically. At the same time the patient began to lose flesh.

On November 18th, 1881, the patient having entered the Woman's Hospital, Dr. Bozeman examined her and diagnosed ovarian cyst. She was also examined by his colleagues, Drs. Thomas and Emmet, both of whom confirmed his diagnosis.

An operation was decided upon, and it was performed on the second day of December, under Listerism. Nothing unusual presented itself in the early stage of the operation. When the tumour was reached, through an incision below the umbilicus, its appearance was nearly that presented by an ordinary unilocular ovarian cyst, except, perhaps, it had a little deeper pearly colour. It was tapped, and two and one-half gallons of fluid were removed. After the greater part of the fluid was drawn off, about two-thirds of the cyst was drawn through the abdominal opening, and then, for the first time, Dr. Bozeman suspected it was not ovarian. He then passed his hand into the peritoneal cavity and found the uterus and both ovaries, and also determined that the cyst had an origin somewhere in the upper part of the abdomen. The abdominal incision was extended upward two inches above the umbilicus. The stomach was then found crowded against the diaphragm, and the bowels were deep in the abdominal cavity below the cyst. The cyst had an extensive attachment, apparently to the transverse mesocolon. After some manipulation he finally reached the pancreas, where he discovered a large vein, subsequently determined to be the splenic, which was very tortuous, and offered considerable obstruction to the operation, owing to its close relationship to the pedicle. Finally, he traced the cyst down until he reached the tail of the pancreas, which was turned up on the side of the cyst, and firmly adherent to it to the extent of two inches. He then proceeded to separate the extremity of the pancreas from the cyst by dissection, and, when completely separated the pancreas spread out and presented its natural appearance.

The attachment of the cyst was at the junction of the outer with the inner two-thirds of the organ, and it had a pedicle three-fourths of an inch in length, and about three-fourths of an inch in diameter. The veins of the pedicle were very large. Having fairly reached the pedicle, he transfixed it with a needle, ligated it in the usual way, and cut it off. The result was that he cut out the bottom of the cyst, as shown in the specimen. The portion of the cyst, however, which remained attached to the pedicle was subsequently completely removed by dissection. The artery which supplied the growth was doubtless a branch of the splenic, and it had attained a very large size—as large as the brachial. The loss of blood was small, and not a single bleeding vessel required a ligature. The fluid which the cyst contained was of a light brownish colour, its specific gravity was 1020, and it had an acid reaction, in that respect differing from the fluid removed from the ordinary ovarian cyst, which is alkaline. The girth of the patient before the operation was 41 inches, and both oblique measurements, from the anterior superior spinous processes of the ilia to the umbilicus, were the same—9 inches. The tumour, with the fluid, weighed 21½ lbs.

The specimen was also interesting in another respect, viz., with reference to the point of attachment, which was almost precisely in the position occupied by the bullet in the late case of our deceased President. The patient underwent

special preparation for the operation. She took salicin, 15 grains three times a day for two weeks. On the morning of the day on which the operation was performed she received 15 grains of quinine with 1 of opium, and when she went upon the table she was thoroughly cinchonized. The patient rallied from the anæsthetic and from the operation without any shock whatever. After the operation she took by the rectum, at intervals of six hours, 10 grains of quinine with 2 ounces of beef-juice, half a drachm of liquor opii comp., and 2 drachms of brandy. On the third day the temperature reached its highest point, 101.5° F., but the pulse never rose above 98. Subsequently the pulse fell to 80, and the quantity of quinine was gradually lessened, but on the eighth day after stopping the quinine the temperature rose to 102.8° F. The quinine was again resumed, 10 grains every six hours, and the temperature, in the course of thirty-six hours, fell to 99.5° F., and subsequently the patient progressed in the most satisfactory manner, and was discharged cured, Jan. 9th, 1882, the thirty-eighth day after the operation.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

CHLOROFORM.—A discussion upon chloroform occupied the whole meeting of the Académie de Médecine.—A member (M. Regnault), believed that the question as to the impurities of chloroform will crop up from time to time as long as another agent possessing the same anæsthetic properties as chloroform, but without its inconvenience and dangers, is not found. The reaction employed for detecting impurities did not, in his opinion, attain the desired end. This reaction consisted of a solution of permanganate of potash with a certain quantity of caustic potash added. This solution gives a fine violet colour when mixed with chloroform, perfectly pure in equal quantities; on the contrary being the case the colour would be green. But he had seen this test tried with chloroform which, though not absolutely pure, was sufficiently so for all intents and purposes, in that it contained no deleterious substances, and the colour obtained was green, so that the test could not be relied on.—M. Gosselin has been convinced for a long time that the accidents which occur under chloroform are not due to the impurities of the agent. These accidents are becoming rarer and rarer in France. According to recent statistics, there is now only one death in 5,200 cases in which chloroform has been used. To avoid these accidents he considered that the better way was to proceed slowly with the anæsthetic. His method has always succeeded admirably. He allows four inspirations of chloroform and then two of pure air, then six of chloroform and two of pure air, eight of chloroform and two of air, and so on. With this method vomiting is rare.—M. Verneuil considered that the best agent for detecting the quality of chloroform was the nose. He was always able to detect by smelling, bad chloroform. He agreed with M. Gosselin in believing that the accidents were to be attributed more to the mode of administration than to the quality of the anæsthetic.—Maurice Perrin was exactly of a contrary opinion. The discussion was closed as it was commenced, by M. Regnault, who, though quite agreeing with the last member, could not deny the fact that certain individuals cannot inhale chloroform, no matter how pure, without being sick.

ELEPHANTIASIS.—At the Société de Chirurgie M. Labbé presented a young girl, *æt.* 20, who was attacked with elephantiasis of the face. The tumour, which commenced at the external angle of the eye, appeared when she was 13 months old, and at the age of 5 it was already considerable. At this period the tumour was operated upon, but returned. M. Labbé thought that an operation might be useful, and

desired the advice of his colleagues. Surgical interference was decided upon.

HOSPITAL MORTALITY.—M. Beisier, in his report on the current diseases in the last three months of 1881, read before the Société Médicale des Hôpitaux, said that the mortality in the hospitals exceeded that of the same quarter of the last nine years, and in proportions beyond the increase of the population. For the entire year the mortality in the hospitals was 15,474 deaths, a number notably superior to the decennial average. Diphtheria had greatly increased, 605 deaths being registered, which showed an increase of 160 over the last quarter of the preceding year. Its mortality, which has been increasing for the last twenty years, has, during the last decade, made rapid strides, so that it has exceeded by a long way in its fatal results typhoid fever and small-pox, and other eruptive fevers.

THE TREATMENT OF HYPOPYON.—Dr. Just, in a German medical journal, recommends *massage* of the globe of the eye, which consists in pressing and rubbing gently the organ with the lower lid intervening. In this way he has succeeded in causing to be absorbed a purulent collection in the anterior chamber. Another oculist has been able to provoke rapid absorption when the hypopyon was mobile by making the patient lie alternately upon the right and left side, and making him change position every hour.

SIGN OF PREGNANCY.—Dr. Delattre writes to the *Gazette des Hôpitaux* upon a constant sign of the beginning of pregnancy, which consists in the almost complete disappearance of the phosphates from the urine. As to what became of the phosphates, the author believes that they are condensed into the bones of the mother, forming osteophites during the first months of intra-uterine life. During the last months the fetus developing rapidly, this reserve of phosphates is largely drawn upon, the bones increase in weight, and the osteophites diminish gradually until their complete disappearance, which generally occurs after the first month of nursing. However, where the mother is weakly and ill-nourished she has, far from forming these reserves, to borrow from her proper substance the elements necessary for the nutrition of the fetus, and consequently her strength becomes exhausted, and the child when born is small and weakly. In this latter case M. Delattre insists on the necessity of giving phosphate of lime during the whole course of the pregnancy.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, FEBRUARY 24TH.

The President, PROF. LISTER, F.R.S., in the Chair.

The Committee appointed at the preceding meeting to examine Dr. Finlay's case of thoracic aneurism presented their report, in which they expressed belief that the tumour was a sacculated aneurism of the ascending aorta, attended with symptoms indicative of aortic regurgitation.

SWALLOWING AN EAR OF RYE-GRASS.

Mr. GODLEE read the notes of a case occurring in the practice of Dr. Ruyard, of Watford, in which a child, *æt.* 2, had swallowed an ear of rye-grass, which had made its exit through a small opening in the back on the left side between the 6th and 7th ribs, three inches from the spine. The grass was shown at the meeting. The patient had suffered in the meantime from spasmodic cough, but as the grass was supposed to have passed by the bowels, the two facts were not connected by the mother. The interval of time between swallowing and the extraction of the piece of grass was altogether 43 days. Mr. Godlee thought that the grass had

probably entered the cesophagus, and not the trachea, and the cough depended upon some little pleurisy.—Reference was also made to a case, the notes of which were supplied by Mr. R. W. Parker, of a child who swallowed a piece of grass, which made its emergence through an abscess, which was set up in the left side, having a distinct fecal odour. The analogy between these cases and those of needle swallowing was pointed out, and a case of the latter was referred to in which a large number had been found by Mr. Godlee *post mortem* in various parts of the body, but exciting little or no inflammation.

Mr. GOLDING BIRD said a few days previously he had received a piece of grass, then covered with pus, which had been swallowed by a girl seven years old, the daughter of a banker in the country. Chest symptoms supervened, and it was thought the patient was consumptive. She was confined to bed, and by and by an abscess pointed externally, through which the grass referred to was extracted. Complete recovery ensued.

Dr. GEORGE JOHNSON on a

CASE OF ACUTE PERFORATIVE PNEUMOTHORAX TERMINATING IN COMPLETE RECOVERY.

A schoolboy, *æt.* 15, ran in a paper chase about twenty miles, and was so fatigued that he fell down exhausted. The two following days he was quite well, but on the 5th November, after running upstairs, he was suddenly seized with pain in the left side, urgent dyspnoea, and great prostration. He was sent to bed, and in four or five hours the distressing symptoms had ceased, but on the following day Mr. Wharton, of Gosport, found all the physical signs of pneumothorax. On the 14th November his father took him to his home at Woolwich, where, on the fifteenth, he was seen by Dr. Johnson in consultation with Surgeon-Major Godwin. He was in bed, but declared himself quite well. Pulse 60, resp. 24, temp. 97. The left side of the chest was nearly motionless, and hyperresonant everywhere except in the interscapular region, where it was slightly duller than at the corresponding point on the right side. Over this space there was a feeble respiratory murmur, but elsewhere over the whole left side there was distinct amphoric blowing, with occasional metallic tinkling, and amphoric echo of the voice and cough. There was no evidence of liquid in the pleura; no dulness at the base, nor splashing succussion sound. The heart was felt and heard distinctly beating to the right of the sternum. With rest in bed and simple diet the physical signs gradually changed. On the 27th November Dr. Godwin reported more movement on the left side; cessation of amphoric blowing and metallic tinkling. Some respiratory murmur on the left of the spine. Heart's impulse to left of sternum. General health excellent. On the 23rd December Drs. Godwin and Stevenson jointly found vesicular murmur over the whole left side, and the heart in its normal position. On the 4th January he was brought to Dr. Johnson, who found that the only difference between the two sides of the chest was a doubtful flattening and diminished respiratory movement in the left subclavian region. He has since gone back to school, and Mr. Wharton writes that, "so far as he can determine, he has perfectly recovered of his pneumothorax." In explanation of the perforated pleura, it is stated that two years ago he had a chronic cough, and it is suggested that as a result of some structural change in the apex of the left lung, the pleural surfaces had become adherent, and that the adhesions were stretched and torn by the violent exertion, so as to cause a rent in the texture of the pleura. Then, as there was no purulent or other morbid secretion which, by escaping into the cavity of the pleura would excite inflammation and suppuration, the ruptured pleura was soon repaired, the air was gradually absorbed, the lung again expanded, and the heart resumed its normal position. Reference was made to a case published by Dr. Stephen Mackenzie (*Lancet*, vol. ii. 1871, p. 259). A man, *æt.* 50, had sudden pneumothorax, resulting, as was supposed, from the rupture of an emphysematous air vesicle. The air was drawn off by an aspirator, and the patient made a rapid recovery. Three cases of recovery from simple pneumothorax have also been recorded by Dr. Wilks (*British Medical Journal*, vol. ii., 1874, p. 770). In none of these three cases was any operation performed.

Dr. DOUGLAS POWELL considered the case interesting in relation to the physical signs exhibited during its progress. The loud amphoric breathing described was unusual, save

in the presence of a free opening. Was it due to modified breath sounds, or to the passage of a to-and-fro air current? Some time ago he had under his care a patient whose stomach was very much displaced upwards, and in whom, a day or two before death occurred, an amphoric sound could be observed, and which post-mortem examination proved to be due to modified breath sounds, consequent on the deformity produced by the distended viscus. He thought that fatal terminations to pneumothorax were to be associated with advanced phthisis; and in one case observed by him, he thought he could ascribe an arrest of phthisical symptoms to the development of pneumothorax and effusion, which terminating in empyæmia with recovery, saved the life of the patient.

Dr. FREDERICK TAYLOR had in 1875 witnessed a similar case of recovery to the one recorded by Dr. Johnson. Patient was a young man, æt. 20, who first complained of pain in his side. He was treated at home, and was subsequently seen by Dr. Taylor after recovery from pneumonia. He suffered, then from dyspepsia, his pulse and temperature were much above normal; heart was displaced; there was dulness at the base of the lung, and the following day fluid, which shifted on motion, was perceived at the limit of the dulness. Under treatment the symptoms improved and gradual progress was made to recovery, which was completely established nine weeks after the onset of the attack. Later, lung disease had been suspected, and the patient had taken several sea voyages with a view to averting the mischief. Before the attack he was quite healthy, and it would be interesting to ascertain how far the pneumothorax might influence the subsequent condition of the affected organ. The attack might probably have been originated by the acute pneumonia which first invalidated him.

Mr. PEARCE GOULD described a case treated by him last summer in the Westminster Hospital. Patient, a boy, had been run over by a cab. Pneumothorax was suspected, and Mr. Gould introduced a small trocar into the back of the chest, air escaped, and a few drops of blood. The lung expanded again, and complete recovery ensued.

Mr. HOWARD MARSH related two cases illustrating the possible origin of pneumothorax. In the first a man had been run over on the chest by a heavy conveyance. Pneumothorax with urgent symptoms was apparent. Mr. Smith then introduced a hydrocele trocar into the cavity and a rush of air came through the tube, giving immediate relief to the patient, but followed by re-accumulation. Death soon after occurred, and at the post-mortem the left lung was found quite separated from its bronchus. There was no other lesion. In the second case, a woman getting out of an omnibus, with her face from the horse, fell backwards, and struck the step with such force that she died within a short time. At the post-mortem the pleura was found to be ruptured by the force of the blow; in Taylor's "Jurisprudence" a similar example is cited.

Dr. TYSON related the history of a woman who died from pneumothorax induced by pyæmia; she had long suffered from an ulcer on the leg.

Dr. COUPLAND suggested the last mentioned case might have been one of abscess. A few years ago he had under his care at the Middlesex Hospital a bank clerk who was suddenly attacked with dyspnoea from right pneumothorax, the chest on that side being full of air. By rest in bed for 14 to 21 days the lung re-expanded; there were signs of effusion, but recovery ensued. Previously to this a female patient had been attacked with sudden pneumothorax which proceeded from bad to worse, with purulent effusion, and terminated in death. This patient gave a family history of tubercle, which Dr. Coupland considered exerted a serious influence on the progress of such cases.

Dr. JOHNSON having stated in reply to a question from the President, that the amphoric sound was heard with both expiration and inspiration,

Mr. LISTER said that the case brought to mind the phenomena attending fracture of the ribs. He was accustomed to illustrate the gravity of the presence of air in the thorax by an experiment to the following effect. He tied a glass tube into the bronchus of a lung obtained from a butcher's shop, and further connected this by elastic tubing with a syringe full of air. Then, incising the lung substance with a pair of scissors, he pressed down the piston of the syringe, the air passing freely out of the wound in the lung. On drawing up the piston, however, it was at once apparent that the air

would not return through the valvular opening in the lung substance, and hence, although during inspiration, air entered the pleural cavity through wounds (usually of a valvular description) in the lung, it could not pass back again by the same channel; and hence the distressing nature of the symptoms induced by these lesions. In Dr. Johnson's case some air apparently did return, as shown by the double amphoric breathing.

Dr. JOHNSON said the blowing sound was caused by the passage of air through the opening. In one case he had found, at the post-mortem examination, that the opening into the lung was closed by lymph. In another case he proved the nature of the sound. It was that of a boy whose chest wall was perforated. On stopping the hole with a finger the sound ceased to be heard. The character of the sub-pleural cavity would determine in great measure the course of the pneumothorax; unequal pressure on the two sides of the chest would suffice to explain the displacement of the included viscera.

Mr. W. SPENCER WATSON read the sequel to a

CASE OF EYEBALL TENSION.

The right eye having been sclerotomised five years ago, the result was reported to the Society in 1880 as being perfectly satisfactory. Premonitory symptoms were then showing themselves in the left eye, and in June, 1881, Mr. Watson operated by sclerotomy on this eye also. The result was not so good as in the right eye, but it was tolerably good. The use of eserine before the operation and after it had been very advantageous. There was a slight contraction of the palmar fascia in this patient, and Mr. Watson having observed the same condition in other glaucomatous cases, was inclined to regard the concurrence of the two conditions as throwing some light on the pathology of glaucoma, and as indicating that an atrophic hardening of the sclerotic coat of the same kind as the shrinking of the palmar fascia might be the initial stage of the disorder. Further proof, however, of this was necessary before the theory could be accepted as proved.

Mr. GEORGE LAWSON considered that evil results followed sclerotomy with more frequency than occurred after iridectomy, while good results were obtained by the latter operation with greater certainty than with the former in cases of acute glaucoma in which no retinal hæmorrhages have occurred.

Mr. McHARDY remarked that the question had been freely and warmly discussed at the late Congress. He agreed with Mr. Lawson, as did all able authorities. In cases where two eyes were affected, it generally happened that the worse was that first operated upon, and hence, whenever the same individual submitted to two operations of which iridectomy performed on the eye most diseased failed, and sclerotomy was performed on the least affected organ, it was impossible to judge fairly on the respective merits of the two plans of procedure. He had recently under treatment, a man, æt. 29, the subject of chronic glaucoma. Cold hands and feet were almost the only other symptom exhibited. On one eye a large iridectomy was done; there was no anterior chamber, the lens impinging on the pupil. Four hours after hæmorrhage necessitated enucleation. Having consulted Mr. Bowman as to the course to be pursued with the second eye, of which the visual field was contracted to 30° above and below, iridectomy was again advised. The result was, unfortunately, bad, and the patient became totally blind.

The PRESIDENT considered Mr. Watson's a successful case of sclerotomy. It was certainly true that tension within the eye set up disturbances due to nervous excitation which was relieved when the tension removed, even for a time.

Mr. WATSON deprecated any desire on his part to overrate sclerotomy against iridectomy. The former operation was on its trial. Reduction of tension in the eyeball was of greater utility by removing pressure on the nerve than by relieving nervous excitement merely. He thought Mr. McHardy's case was one most fitted for the operation of sclerotomy. Under it there was less danger of intra-ocular hæmorrhage, because the aqueous slowly drained away, thereby gradually reducing the tension to which the vessels were subject. He thought the development of a cystoid cicatrix among the most interesting points in connection with his own case.

SOCIETY OF MEDICAL OFFICERS OF HEALTH, IRELAND.

A MEETING of this Society was held at the Royal College of Surgeons on the 15th Feb., Dr. A. O. SPEEDY in the chair.

Dr. CAMERON, Professor of Hygiene and Chemistry, R.C.S.I., Superintendent Medical Officer of Health, read a paper on

HOSPITAL ACCOMMODATION FOR VERY YOUNG CHILDREN SUFFERING FROM INFECTIOUS DISEASE.

The following is an abstract of the paper :—

The epidemic of measles now raging in Dublin, and which, after three months' existence, is now abating, suggests the consideration of hospital accommodation for very young children. The cases of measles which occurred in Dublin since the early part of December numbered many thousands, yet, but a comparatively small number of the patients were admitted into hospital. The disease appears to have been, almost without exception, confined to children, chiefly from two to six years old. It is difficult to induce the mothers of children affected with contagious diseases to allow them to go into hospital. They apprehend that the nurses will not give the little patients sufficient attention. It might be found a good plan to provide for the admission of the mothers of children under two years old into hospital. They would perhaps in the great majority of cases prove better attendants on their sick children than paid nurses. It would, of course, be necessary to provide special wards for mothers and children, and as, during the epidemics, the numbers of patients and their mothers admitted would be a great tax upon the resources of the hospital, pecuniary aid from the local sanitary authorities might fairly be demanded. Under the Public Health Act ample powers are given to local authorities to provide hospital accommodation. To enable hospital authorities to take in large numbers of patients during epidemics would be in the highest sense a measure for the promotion of the public health. There can be no question as to the desirability of promptly removing to hospitals poor persons' children affected with such diseases as scarlet fever, measles, &c. Two advantages result from such procedure—firstly, the patient's chances of recovery are greatly increased by being promptly provided with good medical advice, medicine, and food, together with cleanly surroundings. Secondly, the removal of every child affected with a contagious disease from its dwelling to hospital lessens by one the number of points from which contagion is spread. In the overcrowded, ill-ventilated, and too often filthy homes of the poorer classes, it is difficult to administer properly to the wants of a child suffering from scarlet fever, measles, or other serious disease; consequently the mortality from these diseases amongst the children of the very poor is appalling. When the child of rich parents contracts measles, but little apprehension for the patient's safety is felt. There is a current notion that every one must get measles sooner or later, and that there is no use in trying to evade it; and so far as the children of the rich are concerned, they have little to fear from measles. The great mortality from this disease amongst the children of the very poor is chiefly due to want of proper care during the progress of the disease, and to the filthy surroundings of the patients. A striking proof of the devastation caused by zymotic disease among the poor is afforded by the present epidemic of measles in Dublin. The disease is widespread, and affects all classes, yet hardly a fatal case has occurred amongst the children of the well-to-do people. In January 156 children died from measles within the Dublin registration area, and of these no fewer than forty-eight were the children of labourers, although the latter form only about ten per cent. of the industrial population. Not one child was described as the child of a "gentleman," "physician," "barrister," or other professional man.

The CHAIRMAN stated that he considered it absolutely necessary that in the case of children at the breast both mothers and children should be admitted to hospital.

Dr. DELAHOYD could not take it upon himself to enforce the separation of very young children from their mothers. He thought that both should go into hospital together.

A similar opinion was expressed by Dr. POLLOCK.

Dr. J. W. MOORE, Vice-President College of Physicians, stated that in Cork Street Fever Hospital provision was

made for the admission of the mothers of very young children.

The discussion was then adjourned.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 1, 1882.

MODERN DRESS.

ECCENTRICITIES of costume have in all ages formed a prominent subject on which satirists have expended the magazine of their wit; and in the present day no inconsiderable attention is given to it by those who make it a business to caricature the follies of their fellow beings. It is, however, an all but recent development that is being witnessed now in connection with the efforts made by the medical profession to awaken the public to a sense of the self inflicted evils suffered from absurd compliance with the demands of "fashion." Nor can we feel anything but sincere satisfaction that this question has so far become a "burning" one; and that men of the highest eminence deem it part of their duty to society to issue warnings against the miserable consequences of sacrifices offered to the shrine of appearance. The physical evils of inappropriate dress are so manifest to the physiologist, the constitutional damage they entail so apparent to the physician, the miseries they create so evident to the social economist, that it is rather a matter of wonder they have so long been permitted to continue unchecked and unreformed. Now and again, indeed, individuals in the past have raised a warning voice against indulgence in the fashionable caprices of their time; but never before has a determined attempt to improve public taste and educate public ignorance in

the matter of dress been made that characterises the action of the National Health Society in this respect. On Saturday afternoon last Mr. Frederick Treves, F.R.C.S., of the London Hospital, delivered a lecture before a crowded audience in the Kensington Hall, on behalf of the National Health Society, the subject selected being, "The Dress of the Period." It is gratifying to hear that unusual interest was excited by the preliminary announcements, and that in consequence of a large number of persons being unable to obtain admission to the Hall, the lecture will be repeated on March 18th, in the same place. We shall perhaps be indulging in unlicensed hopes, however, if we permit this result to create in our minds a belief to the effect that the public are at last growing alive to the harmfulness of following the dictates of fashion with the unreasoning submission exhibited in the adoption of its most outrageous demands. It is true the audience which greeted Mr. Treves's demonstrations of modern fashionable follies with applause, indicative of its approval of his denunciations, was chiefly made up of ladies whose claim to be regarded more or less as victims to the Moloch under censure was indisputable; but notwithstanding, it would be the refinement of rashness to expect from them an immediate renunciation of tight waists, cramped feet, and swathed limbs. The hold of these on the lives of those who form "society" is too secure and too steadfastly maintained to permit its being easily removed. We can trust for this happy result to nothing but a general and an intelligent apprehension of the mischief attendant on continuance of the evils which carry such disasters in their train.

We have ventured to express approval of the crusade against fashionable dress, the credit of originating which must rest with the National Health Society. By pursuing the course it has set out upon, this very deserv- ing Association will bye-and-bye be able to reflect that it has successfully combated one of the most destructive and insidious follies of the age; and the method of its action is the best augury for its future success. The ill-consequences set up by improper dress are most familiar to medical men; and medical men necessarily, therefore, are those most competent to advocate reform in customs to the injurious effects of which they are daily witnesses. In the particular folly of tight lacing, for instance, there is probably no practitioner who is not constantly called on to remedy to the evils it produces. In young girls, who, least of all, are calculated to support the strain to which their internal organs are submitted under the cruel pressure of the corset, we have often to deal with piteous examples of the sacrifices required in order to ensure a small waist. Nor is it that they suffer only while young. During their whole after-life symptoms referable to visceral displacement and disorganisation are of frequent occurrence; no woman, probably, who has at any time conformed to this fashion of abdomen-strapping being free from some form of gastric or liver trouble. To what extent, moreover, the craze for "an elegant figure" may carry its victim is scarcely credible, except for occasional proofs afforded at inquests and post-mortem examinations. While it is not unusual to find the liver deeply indented

by pressure of the adjacent ribs, and displaced deep into the pelvis, it has more than once been found that long-continued constriction of the body has resulted in hour-glass deformity of the stomach. Nor need we long hesitate to decide on the influence this vicious form of fashionable sacrifice exerts on the duration of female life, when we reflect on the prevalence among the middle and upper classes of the very diseases which would be induced by persistence in such habits. Gastric ulcer is at least three times as frequent in women as it is in men. Syncope is a common form of weakness exhibited by young women who subject their viscera to the vice-like compression of a corset; and the intestinal troubles set up by interference with the functions of the liver, together with the distributed pressure on the intestines themselves, are among the most productive sources of feminine illness. Indeed, the subject of tight lacing might with advantage be taken as the sole topic for a considerable number of lectures; and the more tellingly the evils it ensures are put before the public, the more convincingly they can be taught to perceive the fatal injury the practice is doing to the race, the more speedily and surely will it cease to be commonly indulged in. We would urge this point—that of the injury suffered through it by the whole race—with especial force. By as much as any woman undermines her own health—it matters not in what manner the mischief is done—to such an extent is she also injuring the physique that will be inherited by her children. Perhaps, by exciting the maternal instinct, more benefit will be derived than by any other means at present devised. At any rate the proposal deserves consideration.

Apart from tight lacing, there are other evils associated with modern clothing that deserve equal attention. Space forbids more than a mention of them now, but we may instance the inadequacy of modern dress to secure either of the two important desiderata—appropriate protection and equable temperature. As Mr. Treves pointed out to his audience, a fashionably dressed woman of to-day is all but nude about the chest and back, at most but a thin, single or double, layer of material protecting these delicate and susceptible regions, while a huge mass of useless clothing is swathed about the hips and legs, and trails in abundant prodigality to clothe the floor around. Again, the disastrous senselessness of "Parisian" shoes, high-heeled and taper-toed, needs no enforcing; but the fashion which insists on them will need a very strenuous and determined opposition ere it is finally conquered.

The question of modern dress, indeed, is, taken altogether, a serious and a pressing one; and the effort that is being made to educate the people into perceiving the frightful errors they are perpetrating by adhering to existing rules regarding it, is one that should receive the earnest support of every member of the profession anxious to witness an improvement in this important respect. We are glad to be able to offer Mr. Treves our hearty congratulations, both on the admirable lecture he delivered on Saturday, and on the unmistakable success with which it has been attended. As his first hope will be for it to be followed by im-

provements in fashionable attire, so are we wishful to see the first dawnings of reason in this respect in the minds of "fashionable society."

THE REFORM OF THE LECTURE CERTIFICATE SYSTEM IN DUBLIN. *

WE learn with great satisfaction that the Council of the Irish College of Surgeons has matured and finally adopted a scheme for securing the *bond fides* of the lecture and hospital certificates presented to them by candidates for their licences. Heretofore, as our readers know, these certificates have—in many cases—represented nothing whatever but money paid, and contained statements as to the attendance of students which were systematically false: On the 20th of October, 1881, the Council adopted a resolution to appoint a Committee "to inquire and report respecting the best means of ensuring the *bond fides* of lecture and hospital certificates as evidences of medical study;" and the Committee then appointed had under consideration replies received in March, 1876, from schools and hospitals throughout England and Scotland, to inquiries then instituted by the Education Committee respecting the method usually adopted to check the attendance of students at lectures and hospital; they also examined the replies from Dublin schools and hospitals to similar inquiries submitted to them by the Branch Medical Council for Ireland, which replies are printed *in extenso* as an appendix to the minutes of the General Medical Council, July 16th, 1880, page 141. On the report of the Committee the Council has resolved in future to recognise no certificates of courses of study unless they fulfil the following requirements:—

(a.) That all lecture certificates shall set forth the exact number of the student's attendances, and the total number of lectures delivered in the course.

(b.) That no lecture certificate shall be received by the Inspection Committee, unless the number of attendances certified shall be at least two-thirds of the entire number of lectures which the Council shall consider sufficient.

(c.) That, as regards hospital certificates, the number of daily attendances certified shall be not less than eighty for the winter session, and forty for the summer session.

The Council has approved the following new form of certificate, which shall, in future, be required by the College:—

SCHOOL OF MEDICINE AND SURGERY.

Lectures on

I hereby certify that Mr. attended
 Lectures of the Course, consisting of
 Lectures, delivered by me during the Session 188...

Signed,

..... Lecturer.

..... Registrar.

In future, in the schools and hospitals in Ireland recognised by the College the attendances of students shall be checked by the following methods:—

(a.) As regards lectures, printed cards indicating the nature of the course, with blank spaces for signature and date, shall be issued at intervals by the lecturer or school

registrar to each student, and one of such cards, properly signed and dated by the student, shall be received by the lecturer from each student when leaving the room after the lecture. Not more than one card shall be accepted at one time, under any circumstances, and all such cards shall be retained until the termination of the course, as evidence of the attendance of the student.

(b.) As regards hospital attendance, in all hospitals recognised by the College a book shall be kept in which each student shall sign his name from day to day; such book shall be taken up by one of the medical officers each morning, half an hour after the commencement of the clinique, and be ruled off and signed by him each day, so that no entry may be made therein, except on the particular day indicated by the signature. In case it appears from the nature of the signatures therein that more than one name has been signed by the same person, the whole of the signatures which appear to be so written shall be struck out by the registrar, and no credit given for the attendance on that day to any of the persons so named. Such book must be kept for future inspection.

In order that the sufficiency of the attendances of the student at lectures and hospital may be fully guaranteed, and presented to the Inspection Committee of the College in proper form, the Council has decided that the various courses of medical study required for each of the examinations of the College be set forth in a "Schedule." The registrar of the schools and hospitals at which the student has attended shall be required to sign a declaration upon such schedule that the entries therein respecting the attendances at their respective school are in all respects correct. The student shall be also required to sign a declaration upon such schedule to the same effect, and furthermore that he agrees that—if the College licence should, after examination, be granted to him on the faith of the entries in such schedule—the diploma may, in pursuance of Clause 18 of the Supplemental Charter, be cancelled and the licence withdrawn, if it be afterwards ascertained that the entries are not correct.

Notes on Current Topics.

Guy's Hospital.

GUY'S HOSPITAL was last week the subject of an attempted censure, most unjustly delivered, by a coroner's jury at Southwark. A patient had been attended in the surgery for what appeared to be only a scalp wound, and was soon after sent away. Before reaching the address he had given, however, he became unconscious; and not being known at this house, the friend who had charge of him conveyed him to the nearest police-station, where he was seen by the divisional surgeon, who ordered his immediate re-conveyance to Guy's Hospital. He never recovered consciousness after admission, and died thirty-six hours subsequently. Post-mortem examination revealed fracture of the base of the skull, and it was on this account the jury sought to blame the officers of the hospital for sending the man away in the first instance, notwithstanding medical testimony showed the fracture could not have been discovered ante-mortem. We are glad to report that the coroner, Mr. W. J. Payne, peremptorily refused to listen

to the complaint of the jury, very properly remarking that he had never known a case in which less blame could be attached to the surgeons who treated the patient. In this instance we cannot but think an unrighteous attempt was made to fasten unmerited disgrace on an unfortunate institution; and we repeat that we regard the action of the coroner as a satisfactory proof of a desire to repress undue willingness on the part of jurors to censure the hospital on every occasion when it is unfortunately brought into notice, whether it deserves it or not.

Waller and De Watteville on the Electrotonus of Human Nerves.

THE results obtained by these observers, after a long and patient investigation, are embodied in a memoir communicated to the Royal Society by Professor Burdon Sanderson, and of which an abstract was read at the last meeting. Many experiments have been made in Germany during the last fifteen years, with a view to demonstrate on living human nerve the phenomena so well known since Pflüger's classical researches. Owing to imperfect methods, however, the results had been as scanty as conflicting. Drs. Waller and De Watteville have succeeded, however, in demonstrating most clearly that the same alterations of irritability which are observed in the excised frog's nerve, both during and after the passage of a galvanic current, occur in the living nerve. Some of these alterations seem, indeed, to be far more marked in the latter than in the former; and the perfected methods they employed gave remarkably clear and uniform results. They tested the irritability of the polarised nerves, not only by means of galvanic and Faradaic stimuli, but mechanical stimuli, also a novel and important feature in their experiments. The consideration of the numerous sources of fallacy to which experiments on the human body are exposed led them to investigate a number of collateral phenomena of interest. Whether any immediate application of their results to electro-diagnosis and therapeutics is possible remains to be seen; but in the meanwhile, we are glad to observe that their memoir is the first contribution ever made in England to the cause of scientific electro-therapeutics.

The Dress of the Period.

On Saturday afternoon, Mr. F. Treves, F.R.C.S., of the London Hospital, delivered a lecture at the Kensington Town Hall, on "The Dress of the Period." The audience was a large and fashionable one, and so great was the interest excited by the lecture, that large numbers of persons were obliged to be turned from the doors in consequence of the large hall being completely filled. The lecture will, it was announced, be repeated on March 18th, in the same place, when those who were unable to obtain admission on Saturday, will have an opportunity of hearing it. The chair was to have been taken by Dr. Andrew Clark, but he was unavoidably prevented from attending, and in his absence Prof. W. H. Flowers, F.R.S., introduced Mr. Treves to the audience. The lecture, which was listened to throughout with marked attention, dwelt on the evil effects produced on the female body by tight lacing, by the absurd manner in which the clothes are customarily worn, and by the compression of the foot into the shoes

insisted on by fashionable requirements. In illustration of the truths laid down, numerous excellently executed diagrams had been prepared, and a model fashionable dress, lent by Messrs. Shoolbred, standing side by side with a beautiful, marble, full-sized copy of Thorwaldsen's Venus, served to emphasise the distinctions drawn by the lecturer between a normal and a fashionably distorted waist. At the conclusion, Dr. W. B. Carpenter briefly addressed the audience.

Torture in the United States.

THE *Louisville Medical News* of January 28th, comments with some asperity on a note with this heading which appeared in our columns a short time ago, and thus affords gratifying evidence that we have succeeded in calling attention in the United States to a matter seriously affecting the credit of the military service of the Republic. The incident, circumstantially reported by Mark Twain, either really occurred or was a creation of the gifted author's fancy. The *Louisville Medical News*, of course, regards it in the latter light, and speaks of it as a bit of extravagant humour. We fail, however, to see the humour of a vivid description of the infliction of intense suffering on an unhappy boy in order to compel him to speak out; and we must remind our contemporary that Mark Twain distinctly states that the experience which he relates is not fictitious, but genuine, and that he takes pains to convince his readers on this point. Supposing, however, that he has been drawing on his imagination for this experience, it is at least curious that he should have endeavoured to heighten its picturesqueness by introducing an impossible incident at the very time when he was labouring to establish the truth of his narrative. Great artists do not often thus offend. For our part, however, we shall rejoice to be assured that "the Innocent at home" did slip for once, and that supposed spies never were *triced* up by the thumbs during the War of Secession.

The *Louisville Medical News* is splenetic in a somewhat school-boy fashion, and retorts on us with a rather transparent *tu quoque* in the shape of a story of an English officer who served in the Kentucky Brigade, and was successful in eliciting information from a Federal prisoner by letting him have an inch of knife in his flesh, saying, "that's the way we manage in India."

The difference between our contemporary's story and ours is just this: that while we give our authority for ours, his is altogether unauthenticated. If he will name the English officer referred to, we shall not credit his anecdote, but be in a position to inquire into it. No British officer would require to be twice convicted of running his knife into a prisoner in India or anywhere else. Our contemporary strangely fails to notice that his anecdote tends to confirm the suggestion which he is so indignant with us for making, that torture was used during the war in the States, for the English officer was in the Confederate service when he ventured to use his knife interrogatively.

DR. MURRELL, Lecturer on Materia Medica and Therapeutics at the Westminster Hospital, has been appointed Examiner in Materia Medica at the University of Edinburgh, in succession to Dr. Lauder Brunton, F.R.S., who has resigned.

Minor Hospital Appointments.

CONSIDERABLE interest having been evinced in our articles on this subject, we now place before our readers the system which obtains in France, taking as our text the special *concours* for the nomination of four *accoucheurs*, advertised to open on March 27, 1882. *Conditions*: All medical men desiring to enter for these appointments must apply to the secretary-general of the Administration of Assistance Publique. The register will be open on February 25, closing on March 11. Those absent from Paris, or prevented by other reasons, can have their names inscribed by letter. As soon as the list of candidates is closed, a jury is formed: each candidate may ascertain the composition of the jury, and if he has any objection he can lodge it in a sealed letter with the director of the Administration. The jury for the appointment of *accoucheurs* is composed of two hospital physicians, acting or honorary, two hospital surgeons, acting or honorary, and three surgeons who have had charge of a special *service d'accouchement*; in all, seven members. Tampering with the jury in any way is forbidden, and is a bar to appointment.

The conditions for the contest are as follows:—1. A written composition on an anatomical or physiological subject; three hours are allowed for this composition. 2. Clinical observation of a woman, *enceinte*, in labour, or recently confined—ten minutes will be allowed for examination of the patient, five minutes for reflection, and five minutes for an explanation of the case to the jury. 3. A theoretical lecture on some subject connected with midwifery, of twenty minutes' duration, after twenty minutes' preparation. 4. Two operations on the dead body. These are called *proofs of admission*.

The next steps, or final tests, consist of—1. A written opinion on a woman suffering from some surgical affection, or on a newly-born child—ten minutes being allowed for examination, and forty-five minutes for composition. 2. An oral, clinical opinion on two women, pregnant, in labour, or recently confined—twenty minutes being allowed for examination, and thirty minutes for an explanation of the cases.

The jury decide by points, twenty being allowed in the first test, and thirty in the latter for each subject. A process of elimination takes place by excluding those who have obtained the least number of marks.

There are advantages in the French system which commend themselves. 1. Merit and industry have a chance of recognition. Influence and interest are of no use in competitions of this kind. 2. Habits of writing and extemporary speaking are cultivated, very important requirements in those who have to teach others.

Now that the struggle for existence is so keen amongst the younger members of the profession, it is important that the fittest should survive; and that appointments in the large hospitals should be thrown open to such a competition as would bring forth the best energies of young aspirants for these appointments. Considerable opposition will, no doubt be raised against a proposal of this nature, as we are so conservative in our ideas and so tenacious of our insular customs. We shall be glad to open our columns to those who desire to ventilate the subject.

Compulsory Notification of Infection.

WE observe with much satisfaction that professional opinion on this subject in England grows apace. Compulsory notification has been rejected by the profession in Liverpool, and condemned at Bolton, and recently the subject has been under discussion in two of the branches of the British Medical Association. At a special meeting of the Lancashire and Cheshire Branch, held on Feb. 8th, it was resolved, after discussion:

"That, in the opinion of the meeting, the compulsory notification of infectious diseases is of great public and national importance. In carrying out this object, the meeting believes that the responsibility of notifying disease should rest with the householders, and that the medical attendant should possess the voluntary power of notifying cases of infectious disease."

A discussion on the subject was also introduced by Mr. Nelson Hardy at a meeting of the South London District of the Metropolitan Counties Branch, held on Feb. 17th, when it was resolved:

"That it be suggested to the Chairman of the Parliamentary Bills Committee as desirable, that the opinion of the profession in the Metropolis should be ascertained in a similar manner to that adopted by the Dublin Colleges, as to the proposals brought forward by the Dublin Branch of the Association, with regard to the notification of infectious disease."

On the other hand, the Town Council of Nottingham have determined to put in force the legal powers which they obtained in 1880 but never used. They propose to limit the notification to small-pox and scarlatina; but we need hardly point out that, if the profession accepts the duty of notification of these diseases it must perform the same function in all infectious cases. We certainly hope they will not submit to be thus burthened with duties inconsistent with their position and inadequately paid for. Notification can be provided for quite as satisfactorily without lading the physician with the duty of procuring and with police-court penalties if he omits to do what he is bid; and we hope the Nottingham physicians will—in the interests of their brethren at large—make their views heard.

A Medical Officer at Fault.

THE medical officer for the Borough of Birkenhead, Dr. Vacher, has recently been made to occupy a somewhat unpleasant position by reason of his over-zealous action in obstructing the sale of adulterated articles of food. Having summoned a tradesman for vending coffee which was asserted to contain a considerable admixture of chicory, the accused denied the adulteration. Dr. Vacher thereupon, somewhat gratuitously, as any competent chemist will allow, insisted that he had proved the existence of chicory by a careful *analysis*. Until this we had entertained the usual opinion that the *microscope* was the only test to be relied on for the detection of this adulteration; and, seemingly, others agree with us, for a certificate attesting the purity of the condemned coffee from Dr. Campbell Brown testifies to the same fact. A certificate of the genuineness of the coffee was submitted from Somerset House; and in face of this cumulative testimony to the worthlessness of the analysis, on the strength of which the tradesman was summoned, the case was of course dismissed; the magistrate adding that

he had very great pleasure in pursuing this course, and giving costs against the corporation in whose service Dr. Vacher performed the analysis.

This incident is a very unpleasant one, not only for Dr. Vacher, but for us, and for all who are called on to condemn his action in the matter. Dr. Vacher is, we believe, a painstaking official, although in this matter he shows a little proneness to over-zealous discharge of his duties. We trust he will learn from the occurrence in which he figures at such disadvantage, to temper his zeal in future with a discretion which will save him from a repetition of the error of which he has this time been undoubtedly guilty. *Verb. sap.*

The Porter Memorial Fund.

It will be in the recollection of many, that when Surgeon-Major Porter met his death at Sherpur, Afghanistan, while engaged as principal medical officer of the Cabul Field Force, that a memorial fund was started to perpetuate the memory of one so much beloved and who had served his country so nobly. The memorial was to take the form of a monument, to be placed in the Chapel of the Royal Victoria Hospital, Netley, and the committee which was appointed on 20th January, 1880, to carry out the design, having now completed their labours, report that the work is now in position, and meets with general approbation. The medallion portrait is of life size, and both it and the other sculptural parts of the monument are of pure white statuary marble, on a back-ground of polished black marble. There was a small balance of £2 9s. 6d. in hand after payment of all expenses, which the committee have handed over to the Netley Charitable Fund.

The Health of Vienna.

THE following data are taken from the last report of the city medical officer, Dr. Kammerer. On the whole there was a moderate increase in sickness during January of the present year. 27 persons died of measles, against 22, Dec. 1881, of which number all were under ten years of age. 13 died of whooping-cough, and 5 of puerperal fever. 321 cases of small-pox were reported, against 270 in the previous month, and 65 persons died of this disease, of which 46 were very young children, and nearly all unvaccinated. 217 cases of scarlatina were reported, against 138 in the previous month; 37 died, of which 28 were under 5 years of age. 154 cases of diphtheria were reported, of which 47 died; 28 of these were under 5 years of age. To each 10,000 of population there were 4 cases of small-pox, 3 of scarlet fever, and 2 of diphtheria. 10 persons died of enteric fever, the same number as in the previous month. In District 1 there were 6 cases, of which 5 were from the House of Detention, from which source were also announced 11 cases of typhus. The total number of cases of typhus was 28, of which 7 persons died. From the 1st to the 10th of February, 16 new cases of typhus have occurred, 13 of them coming from the House of Detention (*Polizei-gefängenhäuser*) in Sterngasse. To combat this house-epidemic, delodgment, disinfection, &c., were at once undertaken by the health authorities. The total number of deaths among the civil population of Vienna in Jan.

1882 amounted to 2018 (inclusive of 136 still-births), against 2,091 in Jan. 1881.

The Horrors of Vaccination.

IN an amusing little article the *St. James Gazette* recently described the vaccination (in America) of the members of Mr. Mapleson's Opera Company. Apparently these worthies regarded the operation in the light of a serious tragedy, and much excitement was created in the bosoms of all at the prospect of facing the vaccine points. "Madame Cavallazzi, as the American journalist puts it, 'bared one of her arms to the keen lancet.' Mdlle. Rossini, Cöbianchi, and Lauri followed the example of Mdlle. Juch, 'who had sacrificed a lower limb.' It was generally remarked that the ladies behaved with greater heroism than the gentlemen. Signor del Puente, so brave when he is playing the part of the bull-fighter in *Carmen*, is said to have had his eyes bandaged, 'so that he should not witness the approach of the glittering steel towards the biceps of his right arm.' Signor Galassi, whom we last saw in London as the terrible Rinnegato in Baron Orczy's opera of that name, prayed during the operation—at least, he assured every one present that 'the fervent words he uttered were indeed a prayer.' Novari fainted and on recovery said he felt sleepy. Monti sent for a Bible, and insisted on his wife's reciting to him 'that portion of the Holy Scriptures referring to the Philistines and the jawbone of an ass.' Campanini was not vaccinated 'nor was his pug-dog.' Mdlle. Vachot wept tears of apprehension, and required two hours before she consented to follow the example of her sister prima-donna. Madame Dotti cried, 'give me the dagger' and nearly knocked the doctor down. Colonel Mapleson faced the lancet like a true soldier, exclaiming at the same time, in the presence of the reporters, who seem to have been admitted to the trying scene, 'This may interfere with cheques and free passes.' Mdlle. Hauk declined the operation, as her husband was away in Pittsburg, and she naturally would require solace. Arditì, with all the strings, most of the brass, and a few of the flutes, was vaccinated on the left arm. One sporting character was vaccinated on both legs, and made a bet as to which leg would 'take' first. The ladies of the ballet, it is stated declined unanimously to be vaccinated, preferring the chances of small-pox to the certainty of immediate disfigurement."

The Case of Dr. Kenny.

MR. CALLAN, M.P., has given notice that he will "call attention to the circumstances connected with the arrest and dismissal of Dr. Kenny under a sealed order of the Local Government Board for Ireland, and to move that the action of the Local Government Board in dismissing Dr. Kenny under sealed order was harsh and uncalled for."

Lunatic Asylums.

MR. STANLEY LEIGHTON has given notice that on an early date he will move in the House of Commons "that the cost of maintaining public asylums should be paid out of the taxes, and not out of the rates, and that private asylums should be abolished."

Rokitansky on the Zwanck Pessary.

A WIDOW, 48 years of age, had worn a Zwanck-Schilling pessary five years, during the last twelve months of which period it had never been removed. It had become rotated, and as may be anticipated, had caused deep ulcerations in the vaginal walls, overlapped by granulations. After some trouble the offending body was removed.

As the Zwanck pessary even yet finds admirers in this country, where it is still sold in the shops, and figured in the catalogues of surgical instrument makers, Professor Rokitansky's opinion thereupon may not be unserviceable. He pointed out that in this case para- and perimetritis might easily have been set up, perforation of the rectum might easily have taken place, and that the causes of these untoward occurrences did not so much lie in the length of time during which the instrument was uninterruptedly worn, as in the shape, form, and mode of action. He concludes as follows:—"According to the principles that govern modern gynecological therapeutics, the Zwanck-Schilling pessary must be pointed out as one that is dangerous and totally useless. It is high time, indeed, that this pessary should take up its permanent place in the gynecological lumber-room. Its only pretensions to value are of an historical nature. Notwithstanding its known dangers, it still, however, here and there finds admirers; it is true that the right choice of a pessary for a particular case requires, first of all, skill, and frequently also not a little patience—requisites that are not at home with everybody."—*Wien. Med. Zeit.*

The Zwanck-Schilling pessary, although not generally known by name in these kingdoms, is objectively known to gynecologists as Zwanck's pessary with three stems, one from each wing and the third running from the hinge.

The Contagious Diseases Act.

THE anti-contagionists are on the war path; they are holding public and private meetings; they are circulating pamphlets and leaflets, and doing all in their power to contaminate the homes of the country, by talking about diseases the names of which have been hitherto unknown to the majority of the women of this country. It is very astonishing that a large number of women who are engaged in this crusade are either spinsters of uncertain age, or wives who are childless.

We have so often spoken on these Acts that we need not repeat the arguments in their favour. We would, however, urge upon the well-meaning, but mistaken women who are connected with this agitation, the harm they may do by the indiscriminate dissemination of literature of this nature among young innocent girls. It would be better for them to do more work directly amongst the class whose persons they are so anxious to protect; to establish refuges and homes where these girls may turn to for assistance, when anxious to leave their abandoned method of living; to bring more personal sympathising aid; above all, to teach their fellow women to be kind to those who have fallen. This form of employment would do more good than ephemeral agitation. We regret to say that female refuges are very badly supported. Women are very severe upon women—many

an unfortunate has been made by the cruelty of her sisters. Turned out of situation after situation, for an offence committed, perhaps, many years before, many a helpless girl has been thrown upon the streets. The offence having become known, the servant or shop-girl is discharged to satisfy her mistress's outraged sense of virtue, and the worst has been accomplished.

Army Medical Department.

SURGEON-GENERAL CRAWFORD, the new head of the Army Medical Department, will leave Calcutta for England on March 12th, so that he will time his arrival almost exactly to enable him to take up his new post on April 1. Dr. Crawford will find plenty of work to do, as the department is by no means in a satisfactory state, notwithstanding all that has been done of late years by Royal Warrants. The proportion of home to foreign service, about two years to five, is still so small that a very large number of surgeon-majors of over twenty years' service retire before they otherwise would, to the detriment of the Service and of the public purse, which is thus burdened prematurely with more pensions.

THE Municipal Council of Villefranche, in the department of the Rhine, has voted the erection of a statue to the illustrious physiologist Claude Bernard. It is to be placed in the square which already bears his name.

AN outbreak of black small-pox of a very virulent type is reported from Trebinje in Herzegovina, a district included in the present revolt. The authorities are said to be taking the strictest precautionary measures against the spread of the disease.

MRS. FRANCES GRANT, who gave a donation of £10,000 last year to found a chair in the new Liverpool University, has now placed in the hands of trustees the munificent sum of £100,000, the interest of which is to be annually distributed among the deserving poor of that town, without regard to class or creed.

AMONGST the Parliamentary Bills which have been read a first time are, a Bill by Mr. Peter Taylor "to repeal the compulsory clauses of the Vaccination Acts," to be read a second time on Wednesday, June 21st; and a Bill for the Total Abolition of Vivisection, to be read a second time on Wednesday, June 28th.

At the quarterly court of governors of the Brompton Hospital held on Thursday last, it was stated that when the new extension building was open it would require an additional income of about £10,000 a year, and the committee accordingly appealed for liberal help. Legacies to the amount of £1,550 were announced.

It is reported that fever has been very prevalent among the troops in Natal, and that the mortality thereby has been somewhat high. At Newcastle the disease appears to have been particularly high; and in consequence of this some regiments have been moved from that place to a healthier locality. The form of the prevailing fever is

said to have been "typhoid;" whether the term is applied as indicating a condition, or a specific disease does not appear from the accounts received.

In the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 30, Bombay 32, Madras 42; Paris 33; Geneva 34; Brussels 27; Amsterdam 22, Rotterdam 39, The Hague 31; Copenhagen 27; Stockholm 22; Christiania 20; St. Petersburg 52; Berlin 23, Hamburg 25, Dresden 23, Breslau 31, Munich 37; Vienna 29, Prague 32, Budapest 40, Trieste 41; Turin 30, Venice 30; Alexandria 29; New York 35, Brooklyn 24, Philadelphia 22, and Baltimore 25. No returns have been received from Rome or Naples since December.

THE annual rates of mortality last week in the principal large towns of the United Kingdom per 1,000 of their population, were—Leicester 14; Derby, Hull, Portsmouth 19; Cardiff, Bristol 20; Birkenhead, Edinburgh, Nottingham 21; Halifax, Birmingham, Leeds, Sheffield 22; Newcastle-on-Tyne, Sunderland, Bolton, Bradford 23; Norwich, Liverpool 24; Salford, Plymouth 25; Huddersfield 26; Wolverhampton 27; Manchester, Glasgow, Oldham 28; London, Preston 29; Brighton 30; Blackburn 35; Dublin 36.

THE rates of mortality per 1,000 last week in the large towns from diseases of the zymotic class, were:—Scarlet fever 3·1 in Sunderland, 2·2 in Nottingham, and 2·1 in Leicester; from whooping-cough, 4·3 in Brighton, 2·2 in Sunderland, and 2·0 in Salford; from measles, 10·3 in Blackburn, 5·3 in Norwich, and 3·8 in Brighton; and from fever, 1·0 in Blackburn and Bolton. The 35 deaths from diphtheria included 12 in Glasgow, 6 in London, 3 in Edinburgh, 3 in Portsmouth, and 3 in Birmingham. Small-pox caused 28 more deaths in London and its suburban districts (including 6 in Croydon), 2 in Brighton, one in Bolton, one in Salford, and one in Leeds.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE CASE OF FISH POISONING AT EDINBURGH.—The members of the family who suffered severely, as if from irritant poison, after eating ling fish for supper, as reported in our last, are now completely recovered. A portion of the fish remaining uneaten was examined by Dr. Littlejohn, but nothing unusual was discovered. An examination of the salt, and the vessel in which the fish was boiled, also gave negative results. Dr. Littlejohn says that in all his experience he does not remember a case in which insufficiently-cooked fish alone produced such results.

HEALTH OF EDINBURGH.—The mortality in Edinburgh for the week ending with Saturday, the 18th ult., was 80, and the death-rate 18 per 1,000. Only 8 zymotic deaths were recorded, none of which were fever.

EDINBURGH UNIVERSITY.—EXAMINERS IN MEDICINE.—The following appointments to vacant additional examinations for graduation in medicine were made at a late meet-

ing of the University Court:—Dr. Byrom Bramwell, F.R.C.P.E. (of Edinburgh), *Clinical Medicine*; Dr. Sidney Coupland, F.R.C.P.Eng. (of London), *Pathology*; Dr. J. D. Gillespie, F.R.C.S.F. (of Edinburgh), *Surgery*; Dr. Wm. Murrell, M.R.C.P.Eng. (of London), *Materia Medica*; and Dr. Richard Caton, M.R.C.P.Eng. (of Liverpool), *Physiology*. These appointments are for the current year; but may be continued by annual re-appointment for five years. The additional examiners in anatomy, practice of physic, clinical surgery, medical jurisprudence, midwifery, botany, and natural history were re-appointed for the current year.

EDINBURGH MEDICAL SCHOOL.—Two new lecturers, we learn, are to be shortly added to the Extra Mural School, in the persons of Drs. Peter Young and Berry Hart. The subject chosen by these gentlemen is that of Midwifery, together with that of the Diseases of Women and Children.

EDINBURGH UNIVERSITY COURT.—At a meeting of the Edinburgh University Court, held on the 20th ult., Principal Sir Alexander Grant presiding, there was laid before the Court an Order of Her Majesty in Council approving of the Council's report in favour of Sir C. Wyville Thomson being allowed to retire from the professorship of natural history on a retiring allowance, and it was reported that the usual publication and intimations had been made as soon as the Order in Council was received. There was also laid before the Court an Order of Her Majesty in Council, granting further monopoly to the University, viz., an alteration of Ordinance No. 8, for making it compulsory on medical graduates to take the degree of Master in Surgery as well as that of Bachelor of Medicine in future.

GLASGOW DEATH-RATE.—The death-rate of Glasgow for the week ending with Saturday, the 18th ult., was 28 per 1,000 per annum, the same as the previous week.

"THE LEAST AND LOWEST FORMS OF LIFE."—The fifth of this season's course of lectures, under the auspices of the Glasgow Science Lectures Association, was delivered on February 23rd. in the City Hall, by the Rev. W. H. Dallinger, F.R.S. There was a large attendance, and the chair was occupied by Dr. Andrew Fergus. The lecturer remarked at the outset that the unity and variety of nature had always been more or less closely perceived by careful observers; but they had never been so wonderfully discovered as now, when immense power of vision had by optical appliances lifted us almost into a new sense. We could now with absolute certainty affirm the universality and changelessness of nature's laws; and, whatever was the subtle difference between matter in a living condition, it was something wholly different, not in degree, but in nature and properties, from matter that was not living. The life stuff in the brain of the philosopher and of the ape—ay, and even of lichen or fungus upon the apple tree—were to chemistry and physics at present precisely similar. But the difference between the lowest form of life and unliving bodies was practically an infinite one. The lecturer traced the life-history of the organisms to be found in a drop of putrescent water, and he illustrated the subject by means of some beautiful diagrams. In conclusion, he stated that these organisms were capable of being destroyed as adults at a temperature of 140° Fahrenheit, but that in fluid heat some of their spore were not more than destroyed at a temperature of 260°. So that we could not infer spontaneous generation in the origin of organisms because they had been in fluids heated to the boiling point of water. All this had a powerful and important bearing when we remembered that some of the most terrible diseases were dependent, as had now been definitely proved, upon the presence of organisms closely allied to those whose history he

had been relating. It had been proved that these were the positive cause of disease, in some cases the disease itself, and at the same time it had been proved that they were capable of modification outside the blood of the patient, which actually changed them into a vaccine that could save them from the disease itself. It was, he thought, a most important matter that we should be definite in our knowledge of a subject like that on which he had been speaking, and he looked forward to the time when we would see that our knowledge of these minute organisms gave us a triumphant power over many of the deadliest forms of suffering which afflicted the human race.

FYVIE.—MEMORIAL TO THE LATE DR. A. F. GREIG.—Soon after the death of this well-known and highly respected physician (in July, 1880), a committee was formed for the purpose of obtaining subscriptions to serve in commemorating his personal and professional worth. The committee, in conjunction with representatives of Dr. Greig's medical friends, have received contributions to the amount of £300, and with that sum it has been resolved to endow a bursary, of the annual value of £12, or thereby, for students of medicine at the University of Aberdeen (his *Alma Mater*), and also to erect a small memorial in Fyvie, which may bear an enduring tribute to the esteem in which he was held by neighbours and patients during a long and arduous practice of 42 years. The form which this local memorial is to assume is still under consideration; but the money for the bursary has already been gratefully accepted by the Senatus of the University, on conditions which provide that it shall be known as the "Dr. Greig, Fyvie, Bursary," the conditions being that it shall be open for competition to all students commencing the second winter session of their medical studies (the subjects of competition being fixed from time to time by the Medical Faculty, and announced beforehand in the "University Calendar"), and that it shall be tenable for three years. It is stipulated that in cases of equality a preference shall be given to natives of the district in which Dr. Greig practised his profession. The first competition is to take place at the beginning of next winter's session.

EPIDEMIC DISEASE AT TORRY.—At a recent meeting of the Town Council of Torry, as Local Authority under the Public Health Act, attention was called to the report of the medical officer, which stated that zymotic diseases—typhoid fever, measles, &c.—had been prevalent for months in the village of Torry, which is only separated from Aberdeen by the river Dee, and from which there is constant communication by fisherwomen and others; and Dr. Beveridge moved that the Board of Supervision be memorialised on the subject with the view of their ordering the Local Authority for the parish of Nigg (of which Torry village forms part) to take steps under the Public Health Act to prevent the continuance of the epidemics. After some discussion the motion was agreed to unanimously, it being stated that under the Public Health Act the Nigg Board could impose any rate of assessment it might be necessary to carry out the provisions of the statute, although they could not impose so large assessment for drainage or water works.

ABERDEEN.—COMBE LECTURES.—St. Catharine's Hall, Aberdeen, was crowded on the evening of Saturday, the 18th ult., to hear Dr. Stirling's lecture "On the Heart." After describing the circulation, the lecturer showed numerous experiments on the action of the valves of the heart, and also on the excised heart of a frog. An image of the frog's heart, whilst the heart was beating, was thrown on a screen, so that the audience could watch the movements of the heart. The image was about nine feet

in diameter, so that the changes of shape of the heart and the order of its movements were visible to every member of the audience. The lecture was brought to a close with a description of the action of the nervous system on the heart, this part being illustrated by apt quotations from Shakespere. The lecturer suggested the desirability of giving instruction in physiology and the elements of surgery to—policemen!

CONCERT IN THE ROYAL INFIRMARY, GLASGOW.—On the 23rd ult., a "residents' concert" was given in the Royal Infirmary, when a number of the medical and other gentlemen connected with the Institution took part in the entertainment. The hall used on the occasion was crowded to the doors with the nurses, patients, and friends, a number of students occupying one corner and filling up the intervals by singing choruses. Romberg's "Toy Symphony" was played. The audience enjoyed the various parts thoroughly, and each item was loudly applauded.

PROBABLE REINSTATING OF DR. KENNY.

WE have authoritative reason for the belief that the Government has, in consequence of the strong representations made by Dr. Lyons, M.P., and others, expressed its disposition to consent to Dr. Kenny being again appointed to the office of Medical Officer of the North Dublin Union, notwithstanding his dismissal by sealed order, if the Guardians please to re-elect him, which, doubtless, they will do. The authorities have shown discretion in thus relaxing their rule in Dr. Kenny's favour, and Dr. Lyons deserves, we think, the thanks of the profession for his exertions in the matter.

WE regret to learn of the sudden and serious illness of Sir Edward Sinclair, Professor of Midwifery in the University of Dublin, and of Dr. Hans Irvine, a well known and much esteemed member of the surgical profession.

Correspondence.

LUCAN SPA, NEAR DUBLIN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am sure it will be of interest to your readers to know that I am making every effort to revive the Lucan Spa, now that the times are not so prosperous as we would wish, and, consequently, people are not in as good a position to travel for their health's sake as formerly. It has, therefore, occurred to me that by placing the enclosed description of this famous Spa before my medical brethren they can at once see that, without much travel or outlay, their patients can enjoy the benefit of mineral waters, as good, if not superior to, the distant ones they have been accustomed to visit. Being about half-an-hour's drive from Dublin, patients can enjoy the privileges of the capital without in any way interfering with their medical course at the Spa.

Apologising for taking up so much space in your valuable journal,

I am, yours, &c.,

GEO. L. B. STONEY, L.R.C.S.I., L.K.Q.C.P.L., &c.
Late Medical Officer and Medical Officer of
Health, Borrisokane Union.

Dec. 9th, 1881.

LUCAN SPAS.

The principal and once famous Spa is situated in the beautiful and picturesque demesne the seat of Lieut. Col. Colthurst Vesey, about midway between the Lucan and Leixlip entrances, and in close proximity to that little para-

dise known as the "Cottage Garden." Through the kind courtesy of Col. Vesey, this demesne is open to the public, and a visit to it is amply rewarded by the splendid scenery it contains. Overlooking the Spa, and only separated from the demesne by the high road, stands that noble pile of buildings lately occupied by, and known as, the Stewart Institution for Imbeciles, or Lucan Spa Asylum, but in years gone by as the Spa Hotel—one of the best hotels as to accommodation, elegance, and appointments, of its day. So much was the water of this Spa sought after at that time, that I believe it was a common occurrence to be entered on the books of the hotel a month before being accommodated with apartments. There is a promenade connecting the hotel with the Spa running beneath the road and opening into the demesne. At the back of the hotel, a little to its right, in a nicely railed-in park (about 3 acres), is situated a terrace of five houses, most comfortable, and having every accommodation; there is also a detached house; their situation is most healthy; being on an eminence they enjoy a dry, bracing air, as well as command a most pleasing scenery. The water of this Spa is of a sulphurous nature, equal, if not superior, to the celebrated Lisdoonvarna, or Harrowgate Spas, as shown by the annexed analysis, kindly made for me by Professor Cameron, who not only examined the water at the Spa, but also at his laboratory, Royal College of Surgeons.

Royal College of Surgeons,
30th day of Nov., 1881.

Composition of a specimen of water taken by me from the Spa at Lucan.

An imperial gallon (70,000 grains) contains the following in grains:—

Total solid matters	37.400
Including			
Albumenoid Ammonia	0.004
Saline Ammonia	0.002
Nitrogen in Nitrates and Nitrites	traces
Chlorine	3.450
Equal to Chloride of Sodium	5.950
Sulphate of Calcium	3.500
Carbonate of Calcium	22.000

This water contains 4.71 cubic inches of sulphuretted hydrogen dissolved in each gallon of water. It is therefore a good sulphur water. It is clear and sparkling, being charged with an abundance of carbonic acid gas. It has a low temperature even in warm water. I hope the use of this ancient Spa may speedily be revived.

CHARLES A. CAMERON, M.D., S.Sc.C.

The action of the above is stimulant, mildly alterative, and slightly diaphoretic; therefore especially beneficial in chronic cases, and in the various forms of skin diseases. Sir H. Marsh used the water with good effect in treating psoriasis, acne, &c. Drs. Hudson and Ferguson recommended its use in chronic rheumatism with enlargements of joints. It has been recommended in secondary syphilis, hæmorrhoidal and some forms of hepatic disease. I myself have used it with great success in eczema. It gently moves the bowels, determines to the surface of the body, promotes the excretion of urine, and strengthens the digestive organs. The Spa is spoken most favourably of by Professors Tichbourne, Mapother, and McNamara, in their respective treatises on mineral waters. During a course of this, as well as all mineral waters, there should be regularity of diet, open air exercise, agreeable society, and perfect rest from all business and mental strain. Dr. McNamara, in his admirable work says: "So fully were the ancients impressed by these important items in a course of mineral water treatment, that the following lines were inscribed over the bath of Antoninus:—

*Curse vacuus hunc adeas locum
Ut morborum vacuus abere queas
Non enim hic curator qui curat."*

There are two other Spas in the neighbourhood, one in the village of Lucan, the other at Louisa Bridge, opposite Leixlip Station, M. G. & W. Ry.; both are of a chalybeate character, and well deserving of a trial.

Lucan and Leixlip are so well known that I consider it quite unnecessary to enter into particulars of their respective attractions. Suffice it to say that there is every facility of reaching them by either the Midland Railway, Great Southern Railway, or by steam tram; the latter, I expect, will be open for traffic early in the New Year. By this route

visitors can enjoy the drive to or from Lucan at a trifling cost. Since the year of the great famine, the Lucan Spas have lost their notoriety; the great hotel had then to be abandoned. It was afterwards taken for a clergy sons' school, and after that as an asylum, for which it was used until 1879. Since then, it is vacant, but excellent lodgings can be procured, either at the terrace, or in the village of Lucan.

RETINAL HÆMORRHAGE AND PREGNANCY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent has put a most important query in your issue of November 30th. There can be little doubt that retinal hæmorrhage would be a most serious complication of pregnancy. We have in the state of the retinal circulation, perhaps, the most ready key to the condition of the vessels generally, both cerebral and renal. The altered state of the blood during pregnancy, more especially when that state passes from the naturally changed condition, and which is inseparably attendant on the pregnant state, into another and far more important one, namely, a hydræmic, or uræmic, or hyper-fibrinoid, and where the small arteries, and capillaries partake of the general consequences which follow frequently on albuminuria, explains at once the reason why we should expect to find in the fine and delicate retinal vessels a frequent indication of danger. This is a danger oftentimes accentuated by the accompanying cardiac deviation in the abnormal force of the ventricular contractions, consequent upon the combined hypertrophic state of the heart, and the irritating effects of the circulating fluid, and the effort to overcome the obstruction in the capillary vessels. Whether we look to the natural consequences of any or all of these morbid blood and vascular accidental attendants in pregnancy, on the resulting effusion or thrombosis, or hæmorrhage, at any stage, from the early months until after labour has terminated, we have the pathological solution of the clinical symptoms, blindness, tinnitus, paralysis, convulsions, and the many other clinical phenomena included in the disorders of pregnancy. Some time since, in a notice of Dr. Wecker's admirable "Lectures on Ocular Therapeutics," I drew attention to this subject thus: (a)

"Nothing could be more convincing than the cases related by Dr. de Wecker in referring to retinal hæmorrhages. It is well known how frequently such hæmorrhages are due to secondary heart mischief which has its source in vascular changes due to morbid blood states, as for instance, in Bright's disease. Most important are such ocular disturbances in pregnancy. This is obvious when we remember the effect produced on the blood by this state, and the relative importance which it has to the safety of the patient, both as an indication of head complications and other hæmorrhagic discharges, either before or during labour."

"I was requested, says Dr. Wecker, (b) to examine a young American lady, twenty years of age, who was in her seventh month of pregnancy, and who complained that her sight had been somewhat dim during the last few days. Her husband begged of me to examine her that very evening, although to do this I had to disturb a large dinner party, which neither the condition of her sight nor health prevented her taking part in. I found that there was a very slight haziness of the retina in the neighbourhood of the papilla in both eyes, and deferred further examination till the next day. At ten o'clock the following morning, the ophthalmoscope showed on the left, near the papilla, a small extravasation, which certainly could not have escaped my investigation of the previous evening. Meeting a colleague in consultation, I informed him of the fresh hæmorrhage in the left eye, and the increased haziness of the papilla, and begged him to allow premature labour to be brought on. I felt convinced that it would not be long before serious brain symptoms would declare themselves, and that in any case this primipara would not arrive at her full time without some accident. One of the most celebrated accoucheurs in Paris was called in in further consultation, but I was unable to convince him of the urgency of this danger. During the night which followed this consultation—that is four days after the first ophthalmoscopic examination—the patient was seized with convulsions, following each other in rapid succession. In all haste Dr. Campbell was sent for, but he did not feel justified in forcibly delivering a patient who lay unconscious and in a moribund condition. Death occurred the following night."

(a) *Dublin Monthly Journal*, April, 1880.

(b) "Ocular Therapeutics," translated by Lytton Forbes, 1879

I am in the habit, in dealing with this subject in my obstetric course, of quoting this most instructive case and another of my own, where a lady desirous of consulting me for a sudden dimness of vision, came to my house, and on finding me out at the time, went away, promising to call the following day. That night she took a warm bath, to relieve her headache, in which she was seized with convulsions, and never rallied, passing into a comatose state. Thus, I think, we have ample grounds, physiological, pathological, and clinical, on which we are justified in advising the postponement of marriage in a case of retinal hæmorrhage, until at least its cause is ascertained, and so far as practicable removed. I am, yours, &c.,

H. MACLAUGHTON JONES,
Professor of Obstetrics, Queen's College, Cork,
Surgeon, Cork Ophthalmic and Aural Hospital.

VACCINO-TUBERCULOSIS!

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—In your last issue appears an article on the transmissibility of tubercle and syphilis by vaccination. I suppose if that were possible, tuberculosis and syphilis would be almost universal diseases, which I am glad to say they are not.

I have had a pretty fair experience as a public vaccinator on and off for nearly thirteen years, and I say that vaccination (properly performed) is incapable of conveying either tubercle or syphilis, or any other disease save and except vaccinia. This may appear a rash statement, and no doubt would be, had I not felt confident of the grounds on which it is made. No doubt many diseases occur after vaccination, which are not of vaccination, as they do after most diseases which are capable of "troubling the waters," and bringing the mind to the surface.

Had the government taken, as they ought to have done, proper precautions that the Acts were carried out with due regard to the welfare of the people, I do not think we should have been troubled with vaccinophobia. At present the vaccination officer is the relieving officer, who has no technical knowledge whatever, and the vaccination inspector has such an enormous district allotted to him that he is hardly able to make one inspection in three years.

I would suggest that there should be an inspector appointed for each county, whose business it should be to attend at least once at each vaccination station during every vaccination period, and that he should have full power to see that the process was carried out in a proper manner, and with due regard to the future health of the vaccinated.

I may state that what I mean by proper vaccination method, is that a child's arm should not be ploughed up as if it were a grass field being prepared for agricultural purposes. That it should no more be said "Dr. So and so made the blood run down to the child's elbow." "He made my child's arm sore by squeezing out the matter," &c. I am quite at one with those who hold that specific diseases have been spread by incapable and careless vaccination. And I am also positive that vaccination pure and simple can no more convey syphilis than small-pox can, than scarlatina can, or than any other contagious disease can, in fact that a disease in conveying its contagium does not make itself the vehicle for conveying another disease also. I do not doubt that if a syphilitic child has vaccination performed on it in an improper manner and the result is an actually inflamed wound, then by taking pus from that wound and inoculating another child with it the result may be highly unpleasant. That vaccination performed as follows is not followed by any disease other than vaccinia, I can say from my own personal experience, viz., The number of "scratches" not to exceed three or four for each pus tube, or more properly vesicle, the punctures to be made only deep enough to cause blood to exude more than sufficient to fill the scratches. The lymph should be perfectly pure and limpid when; lymph is taken all patients with inflamed areola should be rejected, and only those of pearly appearance used, these should be punctured with a very fine instrument, and if the faintest trace of blood or any turbidity appears, don't use it. When old women inoculated small-pox in former times, I do not think there is an instance on record of any disease save and except small-pox resulting therefrom. I may also say that I am informed that syphilis is not unknown among cattle.

I am, yours faithfully,

Whitwick, Feb. 17, 1882.

WILLIAM DONOVAN.

RESIDENT HOSPITAL APPOINTMENTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR.—You have done good service to medical students by calling attention to this hospital grievance. Last month I ventured to write to the *Lancet* on the subject of the appointments at St. Bartholomew's, hoping thereby to attract the notice of the powers that be; but in vain. I therefore readily accept your invitation to join in the discussion you have raised. The disproportion you speak of between deserving students who are desirous of resident appointments, and the number of the latter to be disposed of, attains its maximum at St. Bartholomew's; while the difficulty of selecting from the deserving and desirous those best qualified to fill the coveted posts is at its greatest, and since it is from those who have served on the junior that the senior staff is recruited, the selection or rejection of a candidate for these appointments may make or mar his future prospects.

It would be uncharitable to say the appointments are obtained by a process of jobbery, but it would be difficult to characterise it otherwise. No examination is held to test the capabilities of candidates; little notice is taken of their private career or University attainments; there is no consensus of opinions as to fitness, but the decision rests solely with one man, the physician or surgeon under whom the appointee takes office. It is, therefore, not surprising that a private introduction is a better recommendation than an University degree; and a family connection better than either.

What, then, is the remedy for this state of things? The increase of the junior staff which has been promised will be of little avail if the present rotten system of appointment be not superseded. Let the whole senior staff constitute a committee for the purpose, with the treasurer as chairman; let the previous careers of candidates be discussed, and allowance made for all attainments in the hospital, at the colleges, or at the universities; let a *viva voce* examination at the bed-side (the best of all tests of real knowledge) be instituted; and lastly, let the voting be by ballot, and I firmly believe the result would be satisfactory alike to staff and students.

I am, Sir, yours, &c.,

February 20, 1882.

AN OLD BART'S MAN.

PASS LISTS.

Royal College of Physicians of London.—The following candidates, having passed the required examinations, were admitted Licentiates on Thursday last, Feb. 23rd:—

Alderton, Herbert Charles, Dispensary, Stoke Newington, N.
Bevan, Henry Crook, 29 Frederick Street, W.C.
Cooper, George Frederick, St. Thomas's Hospital, S.E.
Day, Thomas Montagu, Harlow.
De Lom, Henry Anthony, 31 Denbigh Street, S.W.
Fell, Walter, 198 Earl's Court Road, S.W.
Harper, Charles John, 2 Station Road, Minchley, N.
Joseph, John Baptiste Edgar, Trinidad.
Parry, Robert, Festinog.
Prabhakar, Govindrao Bhan, 48 Saltoun Road, S.W.

King and Queen's College of Physicians in Ireland.—At the February Examinations the following obtained the Licences in Medicine and Midwifery of this College:—

MEDICINE.—Henry Vincent Dillon, Fredk. William Elsner, William Dargan Gray, Thomas James Hennessy, James Thomas Laffan, John Patrick Nicolls, Michael J. O'Doherty, Francis Edward Pim, Chas. Fredk. Porter, John Alfred Scott, Charles Henry Freeman Underwood.

MIDWIFERY.—Fredk. William Elsner, William Dargan Gray, James Thomas Laffan, John Patrick Nicolls, Michael Joseph O'Doherty, Francis Edward Pim, Charles Frederick Porter, John Alfred Scott, Charles H. F. Underwood.

The undermentioned Licentiates have been admitted Members:—

John Guinness Beatty. | Charles Coppinger.
J. Barclay Clibborn, Surg. R.N. | Geo. Edw. Twiss, Surg. A.M.D.

NOTICES TO CORRESPONDENTS.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can

now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

MR. W. BERRY.—The notes are interesting, and shall appear in an early number.

MR. J. S. McDONAGH (Hampstead).—We hope to be able to find space for your "Notes on a Case of Idiopathic Peri- and Endo-Carditis" in our next.

MR. B. W. S.—Thanks; by that date there will probably be less pressure on our space.

DR. G. S. B.—We have spoken to a "person in authority," who promises to interest himself in the case, which is certainly a very sad one. When it is necessary to move further in the matter, will write you a private note.

A VICTIM.—Contending interests appear to be so strong that it is difficult to arrive at the truth. We have asked a third and disinterested party to investigate and report.

A COUNTRY PRACTITIONER.—Yes; you will find "Gant's Science and Practice of Surgery" thoroughly reliable; the work is not so well known to country practitioners as its merits deserve.

THE FERTILITY OF THE MULE.—The Arab proverb that "when the mule produces offspring women will become men and men will become women" is now proven to be amongst that large category of rules with an exception, for that great zoological rarity is now on view at the Jardin d'Acclimatation, Paris. It is an African female mule, and since 1874, when she was brought over, she has given birth to five offspring—three to a horse and two to an ass. It is very interesting to compare together the members of this family, unique in origin.

A CAUTION TO SMOKERS.—In a pamphlet recently issued on tobacco monopoly, the author states that in Thuringia 20,000 cwt. of beetroot leaves are used annually for making tobacco. In the neighbourhood of Magdebourg and in the Palatinate they use potato leaves and chicory for that purpose. The Vevex cigars in Switzerland contain no tobacco at all; they are made with cabbage and beetroot leaves, soaked in a decoction of tobacco. The Hygiene Committee of Brealau (Germany) gives the names of five manufacturers at Oban who use every year 1,500 cwt. of beetroot leaves. Besides those leaves, salt, syrup of treacle, sugar, rum, sal ammoniac, tamarinds, saltpetre, potash, aniseed, gum, and dextrine are also used to make both smoking and chewing tobacco and snuff.

MR. J. HENDERSON.—The matter shall be reconsidered.

MR. ALISON.—Tonga is of undoubted value in facial neuralgia, and you may very possibly be successful with it when other remedies fail. It has never, in our experience, produced the symptoms you describe, and we do not imagine you will find them to follow its employment in your case. It may be prescribed either way. Certainly you should obtain it without difficulty in your own town.

ALBERT J.—You probably mean Schroeder van der Kolk. There is a small work answering the description you give by him. The English version was published in Melbourne, Australia. It contains several cases in which clergymen and physicians were victims of the disease. We regret we have not a copy of the book, nor do we think you will easily obtain it.

DOCTUS.—We have no recollection of it, and even if we had it would be of little service to you now. You will be much wiser to adopt a course the reverse of that you indicate; it is never advisable to make enemies where it is possible to avoid doing so.

AN ANXIOUS PATIENT asks us to give him the name of "an honest physician." If the request is *bona fide* we pity our unfortunate correspondent, who must have been mercilessly "quacked" ere he could utter such an appeal. We cannot, however, mention any practitioner by name in these columns; it is against our invariable rule to do so. Any duly qualified medical man should be able to accept the case.

A. F. B.—It is a very disgraceful affair, however it is regarded.

DR. E. F. A.—The clinical consequences are those of most importance. Suppression of urine is always a very serious occurrence, but in the case of an enfeebled subject, it is surrounded with a variety of considerations that might be absent in other circumstances. You may reasonably expect a repetition of the phenomena, and you will be wise to act at once with equal appreciation of the gravity of the situation. We cannot recommend any improvement on your method of proceeding, which in itself speaks well for the excellence of the school you name. This being, as you say, your first trying case, you have acquitted yourself most creditably. We shall be glad to have a history of the case when complete.

MR. HARRIS.—You are required by law to give a certificate of death if you were in attendance on the deceased during his last illness, and can certify without doubt. We do not know of any case in which, under the circumstances you suggest, a medical man has been fined; we only know he *may* be.

DR. WILLIAMS.—Messrs. Churchill will give you the particulars, or you can obtain the book through your local bookseller with less trouble perhaps. We can assure you that you will find it to contain all the information you require.

HUNTER'S PLATES OF THE GRAVID UTERUS.—An almost perfect copy of these rare plates is advertised for sale in our present number. To a bibliophile in search of this work, which is not often obtainable, this notice will be acceptable.

THE SOCIETIES, COLLEGE LECTURES, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—This day (Wednesday), at 4 p.m., Prof. W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Edentata."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—This evening, at 8 o'clock, Annual Meeting: Report, President's Address, &c.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—This evening, at 8 o'clock, Dr. Hubert Airy, "On the Probability that the Infection of Diphtheria is sometimes transported by the Wind."

OBSTETRICAL SOCIETY OF LONDON.—This evening, at 8 o'clock, Specimens will be shown.—Dr. W. S. Playfair, "Notes on Tracheorrhaphy, or Emmet's Operation."—Dr. W. A. Popow (Penna), "On the Corpus Luteum."

ROYAL INSTITUTION.—Thursday, March 2nd, at 8 p.m., Dr. P. L. Sclater, "On Geographical Distribution of Animals."

HARVEIAN SOCIETY.—Thursday, March 2nd, at 8.30 p.m., Dr. Edis, "On Cases of Menorrhagia, with Remarks."—Dr. Cleveland, "On Primary and Secondary Vaccination."

ABERNETHIAN SOCIETY (St. Bartholomew's Hospital).—Thursday, March 2nd, House Surgeons' Evening: The House Surgeons will introduce a Discussion on Head Injuries.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Friday, March 3rd, at 4 p.m., Prof. W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Edentata."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Friday, March 3rd, at 5 p.m., Gulstonian Lectures: Mr. W. Kwart, "On Pulmonary Cavities—their Origin, Growth, and Repair."

ROYAL INSTITUTION.—Friday, March 3rd, at 8 p.m., Mr. A. Tylor, "On Roman Antiquities in London."

ODONTOLOGICAL SOCIETY.—Monday, March 6th, at 8 p.m., Papers by Messrs. W. H. Coffin, S. J. Hutchinson, and Marcus Davis.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Wednesday, March 8th, at 5 p.m., the Second Gulstonian Lecture by Mr. Ewart, "On Pulmonary Cavities—their Origin, Growth, and Repair."

Appointments.

ABBOTT, T. E., L.S.A. Lond., Medical Officer to the Almondbury District of the Huddersfield Union.

BARTON, J. E., M.B. C.S., L.M. C.P. Ed., Senior Assistant Medical Officer, has been appointed Medical Superintendent to the Surrey County Asylum, Brookwood.

BERNARD, A., M.B., Surgeon to the Liverpool Lock Hospital.

FOTHERBY, H. A., L.S.A. Lond., House Surgeon to the Royal Cornwall Infirmary, Truro.

HUTCHINSON, S. J., L.D.S., M.R.C.S., Dental Surgeon to the Dental Hospital of London, Leicester Square.

MARLOW, F. W., M.B. C.S., L.S.A., Senior Assistant House Physician to St. Thomas's Hospital, London.

MCNEILL, J. P., M.D. Dub., L.R.C.S.I., reappointed Public Analyst for the Borough of Tiverton.

PURDON, H. S., M.D. Glas., L.R.C.P. Ed., L.E.C.S.I., Certifying Surgeon to the Belfast District, Belfast.

RICE, B., M.B. Lond., M.R.C.S., House Surgeon to the Warneford Hospital, Leamington.

SUTTON, S. W., M.B., L.R.C.P., M.R.C.S., House Physician to St. Thomas's Hospital, London.

WHITE, E. F., M.B. C.S., L.S.A., House Surgeon to St. Thomas's Hospital, London.

Births.

DUIGAN.—Feb. 22nd, at West Kensington, the wife of D. J. Duigan, C.B., M.D., Deputy Inspector-General of Hospitals, of a son.

ORMEROD.—Feb. 26, at 25 Upper Wimpole Street, London, the wife of J. A. Ormerod, M.B., of a daughter.

Marriages.

BEVOR—LEADAM.—Feb. 7, at the Parish Church, St. Marylebone, Charles Edward Bevor, M.D. Lond., M.R.C.P., to Blanche Adine, third daughter of the late Thomas Robinson Leadam, M.D., of Mortimer, Berks.

DUNBAR—SAUNDERS.—Feb. 21, at St. Paul's Church, Bayswater, James John Macwhirter Dunbar, M.D., eldest son of Surgeon-General J. A. Dunbar, M.D., Indian Army (retired), to Mary, daughter of George Saunders, M.D., C.B.

GORDON—YEATS.—Feb. 8, at Monkstown Church, Samuel Thomas Gordon, Surgeon to the Royal Irish Constabulary, to Fanny Armstrong, daughter of the late Rev. William Butler Yeats, Rector of Tullylish, co. Down.

ROBSON—JAMIESON.—Feb. 21, at St. Mary's-in-the-Bolton, South Kensington, Edward Shedden Robson, B.A., M.R.C.S., L.R.C.P., of Durham, to Edith Isabel, youngest daughter of the late James Young Jamieson, of Gainford House, near Darlington.

YOUNG—RENFREW.—Feb. 23, at Trinity Church, Glasgow, W. S. Young, Esq., of Hong Kong, to Mary, daughter of Robert Renfrew, M.D., of Glasgow.

Deaths.

ALLEN.—Jan. 9, at Secunderabad, India, Richard Maurice Allen, Surgeon 28th Regiment, Madras Native Infantry, son of the late Richard Allen, Wexford.

COUCHMAN.—Feb. 21, at Worthing, R. Couchman, M.R.C.S., formerly of Bedford, aged 63.

DOLAN.—Feb. 26, at Horton House, Halifax, Yorks, Joseph T. Dolan, infant son of T. M. Dolan, F.R.C.S. Ed., aged 7 weeks.

FELLOWES.—Feb. 18, at Chobham, Surrey, Henry Thomas Abdy Butler Fellowes, M.R.C.S., aged 25.

GOODWIN.—Feb. 24, at Ashbourne, Derbyshire, Robert D. Goodwin, F.R.C.S.

GREENHILL.—Feb. 24, at Stoke, Devonport, Louisa, the beloved wife of Surgeon-Major Greenhill, A.M.D., F.R.C.S., who only survived the birth of her daughter six days.

M'CARTEY.—Feb. 24, Florence M'Carthy, L.R.C.P. & S. Edin., eldest son of Eagar M'Carthy, Esq., Dublin, aged 39.

MORELAND.—Feb. 19, at Belfast, Hugh Moreland, M.D., aged 63.

TOOZE.—Feb. 17, Frederick Randolph Tooze, M.R.C.S., second son of the late Rev. H. J. Tooze, of Psychembury, Devon.

YEATES.—Feb. 26, at Walthamstow, Essex, George Yeates, M.D.

The Medical Press & Circular.

CLINICAL LECTURES ON SYMPTOMS.

Delivered in the Wards of the Hospital.

By FREDERICK T. ROBERTS, M.D., B.Sc., F.R.C.P., Professor of Materia Medica and Therapeutics at University College; Physician and Professor of Clinical Medicine at University College Hospital; Physician to the Brompton Consumption Hospital, &c.

LECTURE VIII.—SYMPTOMS CONNECTED WITH THE HEART.—Continued.

THE consideration of the remaining cardiac symptoms presents some difficulty, inasmuch as many of them may be produced in more than one, perhaps several ways, and therefore might be referred to different groups, if we adhered strictly to the plan of describing them sketched in the previous Lecture. I, therefore, think it best, in the present instance, to deviate somewhat from this plan, and after indicating in what further ways symptoms associated with the heart can be produced, to give an outline of the nature of these symptoms.

We have already dealt with two classes of cardiac symptoms, and the rest can be included under the following divisions:—

3. Those belonging to the *functional* group are of great importance. The one *function* of the heart is to circulate the blood. It is the central organ whose action initiates, and chiefly maintains the circulation. Therefore, we naturally look particularly for symptoms resulting from any derangement of this function, but you will readily understand that even when the heart is diseased structurally, it may be able to do its work perfectly well to all appearance, or at any rate so well that no appreciable symptoms can be discovered. Moreover, the phenomena may be of very varied character, according to the exact way in which the function is disordered, and the organs or parts of the body which happen to be affected thereby. It is very important that you should comprehend the different modes in which, so far as the heart is concerned, the cir-

ulation of the blood may be deranged, and they may be summarised thus:—

a. The heart often acts with *excessive force*, with or without increased frequency, as in many cases of mere palpitation, or in those of cardiac hypertrophy. In the latter condition, were it not that it is usually accompanied with other lesions which relieve its undue force, its effects would be much more serious than they are; and, as a matter of fact, the hypertrophied heart may not actually increase the force of the circulation, being merely compensatory to some other condition which interferes with it.

b. On the contrary, *impaired force* of the heart is frequently met with, and this may culminate in complete *failure* of its action. This may be exemplified by the functional disorder producing ordinary syncope; and by the effects of fatty disease or dilatation of the heart.

c. The cardiac action may be *disturbed* in various ways, and thus influence the circulation. For instance, it may be ineffectual and incomplete, although not actually weak in itself; irregular or intermittent; or embarrassed by neighbouring conditions or by conditions within the heart itself, as by pericardial effusion or adhesions, pleuritic effusion, or clotting of blood in its cavities.

d. The circulation is often seriously affected by *mechanical* or *physical* difficulties and disarrangements within the heart, in connection with its orifices or valves. These have to be taken into account in all cases in which any mischief causing obstruction or regurgitation exists at an orifice. Under this head may also be mentioned certain malformations of the heart, in which portions of its septa are deficient, and unusual communications are formed between its cavities.

The effects upon the circulation which may be produced in different cases by the abnormal modes of action of the heart just indicated, are sufficiently obvious, and readily explain the diversity of symptoms resulting therefrom. The effects may be enumerated as (1) Excessive and too forcible flow of blood into the main arteries—namely, the aorta and pulmonary artery, this effect reaching a variable distance along their branches and divisions, and more or less arterial or active congestion being thus produced. (2) Deficient flow into these vessels, often

combined with inequality, the amount of blood driven out of the heart differing in different beats. (3) In the case of the systemic arteries, an undue rush of blood into them, followed, however, by a sudden or rapid emptying in various degrees, in consequence of more or less incompetency of the aortic valves. (4) Overloading of the general venous system, or of the pulmonary circulation, owing to some impediment to the flow of blood, whether due to some mechanical difficulty, especially in connection with the orifices, or to impaired cardiac force. In consequence of one or other of these causes, or it may be both, the circulation behind the difficulty is hindered, a "back-working" effect being produced, and the general venous system, the pulmonary circulation, or both being implicated, according to the seat of the impediment, and a mechanical congestion thus induced. (5) A general languid and sluggish state of the circulation, so that the blood moves slowly throughout the whole body and in all classes of vessels, though this is mainly noticed in connection with the capillaries and veins. (6) Admixture of venous and arterial blood, through abnormal communications existing between cavities of the heart.

Now, you must not forget that some of the disorders of the circulation which I have indicated tend, in course of time, to originate definite lesions in the walls of the vessels, and in the different organs of the body. Therefore, the symptoms resulting therefrom in many cases become permanent, and independent of the cardiac disease which originated them in the first instance.

4. Another element which has to be recognised in the causation of symptoms in relation to the heart is the *blood itself*. In the first place the proper aeration of this fluid may be interfered with more or less, owing to some impediment to the pulmonary circulation; or there is such an intimate mingling of arterial and venous blood through abnormal channels, that in no part of the body is it pure. Then there is often a state of *anæmia* in various degrees, which may be independent of, but is not uncommonly at any rate partly due to cardiac disease. Clotting of the blood, or thrombosis, is liable to occur in certain affections of the heart, and this tends to give rise to grave symptoms. As a consequence of this clotting, or in connection with certain other conditions in the heart, definite emboli may be detached, and conveyed with the blood-current from this organ to other more or less distant parts. Occasionally, materials having septic properties are formed on the inner surface of the heart, and thus becoming directly mixed with the blood, are circulated throughout the entire system, producing the most grave effects. Such are the conditions affecting the blood which have to be borne in mind in different cases, in relation to cardiac affections of an organic nature.

5. In some instances diseases associated with the heart produce *mechanical* or *physical* symptoms, by their effects on neighbouring structures. These are chiefly noticed in cases of considerable pericardial effusion; or sometimes when the heart is much enlarged. In these conditions the parts in the vicinity are liable to displacement or compression, and thus certain phenomena may arise. Here may also be mentioned *rupture* of the heart—a physical lesion which is usually attended with a peculiar group of symptoms.

Having thus endeavoured to point out the modes in which symptoms may be originated in connection with the heart, I proceed now to consider these symptoms individually; and it will again be convenient to arrange them in certain groups.

(1.) You must be prepared for *sudden* or *very rapid death*, immediately due to the heart; or for the occurrence of *sudden grave symptoms* connected with this or with some other organ, but, in the latter case, really of cardiac origin. Sudden death is most frequently dependent upon the heart, and it may be instantaneous, or preceded by subjective præcordial sensations, objective cardiac disturbance, syncopal phenomena or those of collapse or shock, urgent dyspnoea, cyanosis, or other symptoms.

The fatal event may be due to cardiac failure, whether functional or the result of organic disease; arrest of the action of the heart owing to aortic regurgitation, and consequent sudden over-distension of the left ventricle; angina pectoris; clotting of blood in the cardiac cavities, or it is supposed the lodgment in the pulmonary artery of a portion detached from such a clot in the right ventricle; or rupture of the heart. It must be borne in mind that this sudden termination may occur in cases in which cardiac disease, although well-marked, has not been known to exist; while, in other instances, although disease might have been suspected, its signs have been so indefinite that no positive diagnosis has been arrived at. Under certain circumstances, also, unquestionably the heart may fail when it is perfectly healthy, so far as we can discover by the most careful post-mortem examination. Moreover, sudden death from cardiac disease may happen without any obvious immediate cause.

The grave attacks which may supervene, attributable to the heart, but not necessarily fatal, are faintness or actual fainting or syncope; violent disorder of cardiac action; so-called "cardiac asthma," or other form of urgent dyspnoea; angina pectoris; fits of giddiness, which may cause the patient actually to fall; temporary apoplectic or epileptiform attacks, due to congestion or other disturbance of the cerebral circulation; or the cerebral symptoms resulting from actual hæmorrhage into the brain, or from embolism. The heart may certainly contribute by its undue action to the rupture of a diseased cerebral vessel; and embolism of the middle cerebral artery is frequently associated with cardiac disease as its immediate cause. It will suffice at present thus to indicate the occurrences of a sudden and grave character which may be connected with the heart, without entering into a detailed account of all the symptoms, as these will come up for consideration on other occasions.

2. A class of symptoms may be recognised in relation to the heart, of the nature of *general* or *remote subjective sensations*; that is, the patient may be conscious of certain feelings, either throughout the entire system, or in some part at a distance from the heart, and yet dependent upon this organ. They may be constant, variable in degree, or only felt at times. The general sensations include more or less chilliness or coldness of the whole body, culminating in the extreme feeling of this nature noticed in some cases of congenital malformation with cyanosis, the patient feeling cold even in the hottest weather, and crouching over the fire; a sense of weakness, ennui, languor, apathy and indisposition for exertion or occupation, want of vitality and vigour, and fatigue easily induced; and a tendency to faintness. The local sensations are coldness or clamminess of hands and feet, but especially the latter; throbbing about the head, face, or neck; headache, or a feeling of fulness or heat in the head; vertigo; temporary or permanent disorders of vision; tinnitus or noises in the head, and disturbances of hearing. These symptoms depend mainly on the way in which the heart is acting, and the blood circulating; but partly, in some instances, on the condition of the blood itself. Some of them are not uncommon in functional cardiac affections.

(To be continued.)

ON OSSEOUS ANCHYLOSIS OF THE HIP-JOINT TREATED BY OSTEOTOMY. (a)

By WILLIAM STOKES, F.R.C.S.,

Professor of Surgery, Royal College of Surgeons, Ireland;
Surgeon to Richmond Surgical Hospital, Dublin.

WHATEVER differences of opinion may exist as to the surgical merits of resection of the hip-joint, these can hardly be said to exist as regards some of the other kinds

(a) Read before the Surgical Society of Ireland. Discussion will be found on page 203.

of operative interference at this articulation, when one of the results of injury or arthritis, viz., complete ankylosis altering the position of the limb so as to render it practically useless to the patient, is present. This form of complete angular ankylosis, sometimes oddly termed "vicious," is not, in my experience, one often observed. A well-marked example of this condition was under observation in the Richmond Hospital during the early part of last spring; and a brief record of the case, along with an account of the operative treatment I adopted, has, I think, points of surgical interest not unworthy of record.

Nicholas B—, æt. 14, was admitted into the Richmond Hospital under my care on the 1st of March, 1881. He was a fairly-nourished youth. The right thigh and leg were, however, much atrophied, and this process involved largely not only the soft structures of the limb, but also the bones, arrest of development in the tibia on the affected side, as well as the femur being well marked. The thigh was strongly flexed, and rigidly fixed in that position, which rendered the limb perfectly useless to the patient. Locomotion could only be effected by the aid of crutches, the assistance of which the patient invariably had recourse to. The result of careful measurements showed that in length the affected limb was shorter than its fellow by three inches and one-eighth. Both on the lateral and posterior portions of the upper part of the thigh were found numerous cicatrices, indicating the pre-existence of sinuses, which, as I was informed by the patient's mother, for several years gave exit to a profuse purulent discharge. These, however, had at the time of the patient's admission into hospital completely healed. The mother stated that the disease commenced nine years previous to this, and gave evidence in favour of it having originated from injury. On observing the child walking lame, and complaining of pains referred to both the hip and knee, she brought him to an hospital of this city, where, however, he was, owing to alleged carelessness on the part of his nurse, only allowed to remain for three weeks. Of the treatment adopted at this stage of the disease all I could ascertain was that blisters were applied to the affected hip. After this, for seven years, the child was kept at home, and without any regular surgical treatment. An abscess formation then occurred, which opened at the front of the thigh. This was treated mainly by poultices, of various and strange composition, unnecessary to indicate, recommended at different times by irregular practitioners. The case not improving, and the limb getting more flexed, the patient was in 1879 brought to an hospital, when forcible extension was recommended and tried, but without success. After this fresh abscesses formed, opening chiefly at the back of the thigh. The patient remained three months in hospital, during which time four ineffectual attempts were made to forcibly straighten the limb. Excision of the head of the bone was then proposed, but to this suggestion the mother would not assent. The patient was then brought home, and kept there until February 14th, when he was brought to the Richmond Hospital in the condition I have indicated above, and placed under my care. Had so many attempts not already been made to forcibly extend the limb, I should probably, in the first instance at all events, have had recourse to this line of treatment. But having regard to the facts of the absolute immobility of the limb, and also that the surgeon under whose care the patient had been is a person of recognised discretion and skill, I deemed it inadvisable to make any further attempts in this direction. I came to the conclusion, therefore, that some other operative measure was indicated, such as division of the neck of the femur, or, if necessary, excision of its head. I informed the patient's mother of the view I took as to the operative treatment to be adopted, and she at once left the case unconditionally in my hands.

On March 9th, 1881, I operated in the following manner:—The patient being etherised, I made a straight incision behind the great trochanter, commencing three-quarters of an inch above it and carrying it downwards

for a distance of three inches and a-half. From the upper portion of the incision I carried it in a curved direction upwards, forwards, and then slightly downwards—the whole incision being thus somewhat crozier-shaped. This line of incision I adopted partly to give myself plenty of space to determine the actual condition of the parts, and partly because I knew by experience it is a convenient one to adopt, in case I deemed it desirable to excise the head of the bone. The soft structures being then dissected off the trochanter, and portion of the bone immediately below it by scalpel and periosteal raspator, I then passed my finger into the wound to ascertain the condition of the head and neck of the bone. The former I found rigidly fixed to the acetabulum, the latter shortened and atrophied. There was no evidence whatever of any part of the bone being in a state of softening. I then passed in a medium-sized osteotome, and by a few sharp taps of a mallet succeeded in dividing the neck of the femur. Notwithstanding this, I found it impossible to satisfactorily straighten the limb, owing to muscular contraction, chiefly of the adductor muscles. A subcutaneous tenotomy, however, at once overcame this obstruction, and the limb then could be satisfactorily extended. The wound was then carefully washed out with a 1-40 solution of carbolic acid, a drainage tube inserted, and the edges brought into close apposition with numerous points of interrupted catgut suture. The usual Lister dressings were then applied. The wound healed without pus production. During the convalescence of the patient a moderate extension of the limb was kept up, mainly by my double-threaded screw extension splint. After six weeks the patient was able to get about the ward without the aid of crutches, but with that of a stick. This latter was subsequently discarded, and the patient soon after returned home. Three months after this I found the patient healthy and strong, and able to walk with facility without stick or crutch. He suffered no pain, and there was distinct evidence of the formation of a false joint at the site of the operation. The muscular development of the affected limb was greatly improved, the limb straight, and the patient stated he was able to walk without inconvenience a distance of over three miles. He was shortly after this admitted into the Artane Industrial School, where he still is.

As regards osteotomy as a treatment for angular ankylosis of the hip, a few historical details connected with it may be mentioned. The credit of having first suggested and practised the operation for the cure of this deformity, formerly considered a condition that necessitated amputation, is due to Dr. J. Rhea Barton. He, as we learn in Dr. Agnew's classical treatise, performed the operation in 1826, in the case of a sailor, by exposing the trochanter by means of a crucial incision and dividing it with a saw. The modifications of this procedure were those of Rodgers, who excised a wedge-shaped piece of bone between the trochanters, and establishing a false joint at this situation; also that of Sayre, who excised a segment of bone convex above and concave below, so as to imitate a ball and socket joint. In connection with this subject, I am glad to be able to exhibit a cast of the false joint, which was obtained after one of Prof. Sayre's cases, which cast he kindly presented to the Museum of this College. The post-mortem in this case showed a capsular ligament, synovial membrane, and two round ligaments. The next modification is that of Mr. Adams, who, as all here know, divides the neck of the bone subcutaneously by means of a peculiar-shaped saw, which he devised for the purpose. However signal the advantages of subcutaneous osteotomy may have been in what may be termed the pre-antiseptic era of surgery, they can hardly be so regarded now, and it has this disadvantage, that the surgeon cannot possibly obtain any accurate information as to the existing condition of the parts when he operates through a mere puncture of the skin. There is another point connected with Mr. Adams' operation which I think worthy of note. I am not aware that in any of his cases has a movable joint been obtained. This, possibly, may be owing to the presence of bone fragments in the wound, resulting from the action of the saw, and such acting as

centres of ossification, may possibly be antagonistic to the formation of a pseudarthrosis. Actuated by this idea, I determined to divide the neck of the bone in the case I have brought under your notice this evening with a chisel rather than the saw. This was, I have heard, done first by the late Mr. Maunder, of London. The method is one which I think undoubtedly possesses advantages over the modifications of Rhea Barton's operation, which I have already briefly alluded to.

There are several important questions involved in the consideration of such a case as the one I have just recorded—questions bearing on the all-important and still unsettled one, as to the best means of dealing with coxo-femoral arthritis in the child—a disease of such frequent occurrence among the badly-clothed and badly-nourished poor of this country, one, I may say, under constant observation and treatment in the surgical practice of all here. In this case had issues been inserted, or blisters applied, had tapping the joint in the early stage of effusion into the joint been employed, had long-continued extension or drainage by caustics, or rigid fixation been applied, or lastly, had resection of the joint been performed, would the chances of the patient having a more useful limb than he has at present have increased or diminished? To such a question it must regretfully be admitted—and all conscientious surgeons will, I feel sure, endorse what I say on this point—that a definite answer could not honestly be given. No one here has had, so far as I am aware, a larger experience of the merits or surgical value of hip-joint resection than our Vice-President, and that experience, of which he gave an able account at the debate on this subject at the International Medical Congress, was not such as to encourage surgeons to advocate or practise, unless in very exceptional cases, this particular excision.

The all-important and still unsettled question as to the best means of dealing with the early stages of coxo-femoral arthritis, not only with a view to cure, but also to the prevention of deformity, and the comparative merits of forcible extension, resection and osteotomy, when the particular and rare form of deformity which the case I have brought under the notice of the Society this evening afforded so signal an example of, is present, are topics which must ever be of the deepest and most abiding interest to the surgeon.

NOTES OF A CASE OF EARLY MENSTRUATION.

By WM. BERRY, M.R.C.S. Eng. & L.R.C.P. & S. Ed.
Hon. Surgeon Royal Albert Edward Infirmary, Wigan.

CASES of early menstruation in this country are sufficiently rare to make them worthy of record when they do occur.

By early menstruation I mean cases in which the menstrual *menstrum* is properly and perfectly established. I do not include at all those cases which occur now and again in infants of from three or four weeks old and suffer now and again from hæmorrhage from the genitals, but have no symptoms common to the function of menstruation.

I find from a table given by Professor Leishman in his work, page 88, that in England there are recorded 14 cases under 10 years of age by Rolleston, Lee, Whitehead, and Murphy, and in the *Lancet* of 1866, vol. ii., Dr. Allbut gives a list of cases supplied to him by Dr. Aveling.

A similar case to the one I am about to record is published in the form of a letter to the *Lancet*, of July 20, 1878, by Mr. Tetley, of Keighley, the age in that case being 5½ years, and menstruation commenced 12 months before.

The following are the notes of my case:—

On June 17, 1880, I was consulted by the parents of A. B., aged 6 years and 2 months, owing to a periodical discharge of blood, which rather alarmed them, although she did not suffer in health.

Her mother informed me that she noticed the discharge 10 months before; that would be at the age of 5 years and

4 months, and it had recurred regularly ever since at periods varying from 3 to 6 weeks, and generally lasted three days. The girl at these times often complained of pain in her belly, and looked very pale.

On examining her I found her with well-developed mammary glands, and the external genitals also well developed, and covered with soft rudimentary hairs. Although the discharge was now absent, I was satisfied from the description that this was a case of early menstruation.

I told her mother not to be uneasy about the discharge, but to watch her and look after any little ailment she might have, and inform me if the discharge again recurred. She did not see anything more till September following, being a period of three months. Since then, however, she has menstruated regularly, the longest interval being 5 or 6 weeks. In every other respect the girl is strong and healthy.

Clinical Records.

MIDDLESEX HOSPITAL.

Cerebral Abscess—Trepining—Death.

Under the care of Mr. GEO. LAWSON.

[For the notes of this case we are indebted to Mr. W. ROGER WILLIAMS, F.R.C.S., Surgical Registrar.]

THE patient was a little girl, æt. 12, who was admitted into the Hospital on Dec. 31, 1881, complaining of headache and sickness. Five weeks ago she fell and cut her head down to the bone. Her mother says she has lately had "fits," attacks of vomiting, and a weakness of the right arm.

The patient is a delicate-looking child. She has vomited twice since admission, and has a bad frontal headache with vertigo. There is a small, almost completely healed, wound on the right side of the forehead, just at the spot where the hair commences. The pupils are normal. No optic neuritis. Bowels confined. Pulse, respirations, and temperature, normal. After a week's rest in bed all these symptoms subsided, and the patient seemed quite well—talking, reading, &c.

On the morning of Jan. 11th, the headache and vomiting recurred. She continued in this condition for three days, then she grew dull and drowsy, and had twitchings of the upper and lower extremities. There was no fever. Coma gradually supervened.

On Jan. 15th Mr. Lawson trephined at the seat of the injury. There was no "puffy swelling," or other local indication of intracranial suppuration. No fracture could be detected. A rather small-sized trephine was used. The bone was soft, especially the diploë. The dura mater was congested; there was no cerebral pulsation. A canula was thrust through it, and nearly 2 ozs. of pus evacuated. It was at the time believed to have come from between the dura mater and the brain. There was scarcely any bleeding. The patient vomited several times the night after the operation, but not subsequently.

On the following day she was semi-comatose and drowsy, but able to answer questions rationally when shouted at. The eyes were closed and averted from the light; the pupils normal. Frequent twitchings of the limbs occurred. Pulse, 80—sub-intermittent, full; temperature, 98.2° F. As no discharge escaped from the wound, Mr. Lawson incised the dura mater and cautiously inserted the knife to the depth of about half an inch. By this means a little pus was evacuated. Throughout the evening and night she continued in the same state. Towards morning the coma deepened, and she died thus at 8 a.m.

Autopsy, thirty hours after death: Rigor mortis well marked. On clearing the soft parts from the outer table of the skull, in the vicinity of the aperture made by the trephine, which is just above and external to the right frontal eminence, no fracture could be detected; but the bone had lost its proper colour, and was softer than usual. Its inner table was rough and red near the perforation. The diploë was very soft and red. Seen through the trephine aperture, the dura mater is congested, and there is a small hole at

about its middle through which thin pus oozes. At this spot the dura mater is adherent to the surface of the brain, over an area about the size of sixpence, corresponding to the forepart of the mid-frontal convolution, which is also perforated by a small hole. The brain and its membranes are congested, and the convolutions markedly flattened. In the right frontal region there is great deformity. The convolutions of its upper surface are not only flattened, but the normal convexity of this part of the brain is replaced by a shallow concavity. Over this region fluctuation is very manifest. The lightest palpation causes escape of pus from the small hole just mentioned. There is evidently an abscess in the substance of the brain. The inner aspect of the frontal lobe bulges in a very marked manner across the median longitudinal fissure, encroaching on the corresponding part of the left hemisphere, in which there is an indentation. On making a vertical section of the right prefrontal region, at right angles to the longitudinal axis of the hemisphere, after the manner of Pitres, an abscess, the size of a small orange, was exposed, which has destroyed nearly the whole of the white substance of the centrum ovale, in the midst of which it is situated. It has a thick, tough capsule quite impervious, except at the spot where the canula has penetrated. The grey matter of the convolutions is not destroyed, though in several places only a very thin layer of white substance intervenes between it and the abscess-wall. Posteriorly, the abscess comes near to the anterior extremity of the lateral ventricle, and the adjacent parts of the basal ganglia; but it does not actually encroach on either of these parts. However, the tissues outside the abscess sac, occupying the intervening space, are in a state of acute red softening—bordering on complete disintegration. Probably, this was the cause of death, and of the symptoms observed during life; the abscess itself having caused scarcely any obvious disturbance. In other respects the brain was healthy; the liver was congested; the other organs were normal.

This case illustrates the fact pointed out by Dr. Ferrier, that removal or destruction of the antero-frontal lobes is not followed by any definite physiological results. It is also in accordance with recent pathological observations which point to the same conclusion.

Transactions of Societies.

SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society of Ireland was held on Friday evening, Feb. 10th, in the Albert Hall, Royal College of Surgeons.

Mr. B. WILLS RICHARDSON, F.R.C.S., Senior Member of Council present, in the chair.

Mr. WILLIAM THOMSON, Hon. Sec., read the minutes of the previous meeting, which were confirmed.

Mr. WHEELER exhibited the
ARTICULAR ENDS OF THE RIGHT FEMUR AND TIBIA, WITH
PATELLA,

which he removed from a lad, *æt.* 13, when excising his knee. About three years before the boy came into hospital he received a severe blow from a school-bench on the patellar region. Pain, accompanied by considerable swelling, supervened. He could always walk on the injured leg, except during frosty weather. Measurement showed, below patella of healthy knee, $9\frac{1}{2}$ inches; diseased knee, 10 inches; sound knee, on patella, $11\frac{1}{4}$ inches; diseased knee, $12\frac{1}{4}$ inches; sound knee, above patella, $10\frac{1}{2}$ inches; diseased knee, $11\frac{1}{4}$ inches. Very little pain was complained of on pressure, except at the lower and external angle of the patella. When the tibia was pressed against the condyles of the femur considerable pain resulted. The limb was habitually semiflexed. On examination of the parts produced, it was found that the synovial membrane well represented the pulpy degeneration of Sir B. Brodie. Both condyles of the femur were carious, the external more than the interval, and the space between the condyles was more diseased and more worm-eaten in appearance. There seemed to be marked condensation of the deeper portion of the bone around this ulceration. The semilunar cartilages were eroded. Beneath could be seen the head of the tibia, carious.

The bone at the edges of the cartilage was carious. The patella was healthy.

Mr. H. G. CROLY showed a specimen of

EPITHELIOMA OF THE OESOPHAGUS.

The patient, *æt.* 60, was admitted into hospital on the 22nd December last. It was remarkable how little pain he suffered. There was syphilis in the history of the case. On trying to swallow the patient made spasmodic efforts to get fluid down; but it was immediately rejected. He was kept under observation a few days, being able to swallow a certain amount of soda-water and milk. At last the symptoms became so aggravated he could scarcely swallow anything at all. Having expressed his opinion that the case was one of cancerous stricture of the oesophagus, Mr. Croly proposed the operation of gastrostomy to save the man from death by starvation. The operation was performed, with the result that he lived only a day after it. In the specimen might be observed the adhesions between the peritoneal surface of the stomach and the abdominal walls, which were very perfect. The disease was seen in the form of an epitheliomatous mass, and Dr. Abraham had so declared it to be a cancerous type. The situation of the annular stricture was a little below the crossing of the left bronchus. There was no disease of any other surrounding parts. The specimen was interesting in connection with the operation of opening the stomach. His only regret was that he did not open the stomach immediately on the admission of the patient into hospital; but he had had no previous experience of gastrostomy.

Mr. THORNLEY STOKER exhibited a specimen of

COMPOUND DISLOCATION OF THE ANKLE,

which was so severe as to require amputation. The dislocation was of the most usual form, that of the foot inwards and of the two bones of the leg outwards. In addition to the dislocation and laceration of the soft parts, the malleolus of the fibula had been fractured transversely on a level with the transverse surface of the tibia, while the malleolus of the tibia was similarly broken off from its attachment and remained connected in its usual position on the inside of the foot. There was, however, this difference, that whereas the fracture of the fibula was quite transverse, that of the tibia extended obliquely upwards and inwards. The injury was produced by a kink of chain catching round the man's leg while anchor was being weighed.

Mr. LAMBERT H. ORMSBY exhibited two specimens of Scirrhus Breast.

The discussion on Mr. W. Stokes' paper on

DIVISION OF THE NECK OF THE FEMUR IN CASES OF ANCHYLOSIS,

then took place, an abstract of which paper will be found on page 200.

Mr. BENNETT considered the question raised was as to the *modus operandi*—whether they should follow Adams' operation, consisting of the subcutaneous section by a saw introduced through an opening the width of its own blade, or that of Mr. Stokes, by a free and open incision. Unquestionably at the time Adams introduced his operation it was the only one admissible, as under the older system of operation he did not think any one would undertake the section of the neck of the femur either in child or adult with a free incision; but now there was the security of antiseptic treatment. Therefore, the point was as to whether the osteotome or the saw was the best instrument to use. So far as the child was concerned in this case, there could hardly be two opinions about it. The saw must produce a certain amount of detritus from the bone, which could not be an advantage, and hence, if an instrument could be got to divide the bone without producing such sawdust it would be preferable. In the case of a child, where the pressure of the hand would take the osteotome through the bone, there could not be any question as to using that instrument; but in the case of an adult, it was extremely difficult to take an osteotome or saw through the bone, and he would prefer the osteotome, because no *debris* would be left by its action. It was obvious, therefore, that Mr. Stokes' method was the best, as combining two advantages—first, that of a free and open incision, guarded by the antiseptic proceeding; and secondly, by using the osteotome rather than the saw there was a less amount of irritation in the wound, and nothing was left behind.

Mr. WHEELER said, as to the point which Mr. Bennett

raised about the saw, no doubt that to perform Adams' operation strictly the objection would apply; but by making a free opening the *débris* could be washed away, and in that case the saw would be a better instrument than the chisel. But that was not the point he would dwell upon; it was rather the important fact that the boy was present to be examined, so that they could see whether there was any amount of shortening, whether there were any sinuses, and so on. Again, it was important, in a surgical point of view, to see, under the guidance of statistics, whether they were justified in attempting operations of that class at all or not. Of course he was aware the operation was performed by Rhae, Barton, Bardwell, Adams, and others. But the point was to see the result themselves. He rather emphasised that, inasmuch as he knew there were many cases recorded and put down as successful in which the result was not satisfactory.

Mr. STOKES moved that the standing orders be suspended, in order that he might exhibit the patient.

Mr. BENNETT seconded the motion.

The CHAIRMAN put the motion to adjourn for ten minutes in order to examine Mr. Stokes' patient.

The motion was put and carried *nem. con.*

[The boy was then introduced and examined.]

Dr. HEPBURN asked what was the date of performing Mr. Stokes' operation, the successful result of which they had witnessed?

Mr. STOKES—Last March.

LITHOTOMY.

Dr. ANTHONY H. CORLEY said he wished to exhibit as a specimen a vesical calculus which he had extracted by the lateral operation nearly three weeks previously from a little boy, *æt.* 8. As there was some difficulty and delay in getting into the bladder, he would relate the case with observations, and trusted it would give rise to an interesting discussion. He might remark that the patient had made a complete recovery; therefore, there might be less hesitation in discussing the difficulties of the case, as operations in which obstacles were encountered were often more instructive than those in which the procedure was rapid and brilliant. When the patient was placed in the usual position, the staff, an ordinary one, size No. 6, was introduced (an attempt to pass a larger one, of Dr. M'Donnell's pattern, having previously failed). Unfortunately, at this stage the urine escaped, it was hoped partially, but, as it afterwards turned out, completely. The usual first incision was made, the groove in the staff was reached without much difficulty, the urethra was incised, and he then changed his knife for a blunt-pointed one. There was, however, great difficulty in passing this through the urethral cut into the groove, so much so, that he laid it aside and again introduced the sharp-pointed knife into the groove and passed it along into the bladder. When he believed he had made a sufficient incision, he tried to pass his finger along the knife, but failed to do so. The tissues seemed more ready to be pushed before the finger than to allow it to pass through the incision. At the furthest point, where the finger could touch the staff, he could distinctly feel a membrane across the groove, and it occurred to him that this must be the lower wall of the urethra which the knife had pushed before it and not thoroughly divided. He then passed a probe along the groove, and could feel from the inside the membrane which he had already felt with his finger. Withdrawing the probe and taking up an ordinary Blizard's knife, guiding it with his finger as far as possible, and then following the groove, he divided the membrane and made a sufficient section of the vesical neck to allow his finger to pass into the bladder. Having felt the stone with his finger—and not till then—he withdrew the staff, introduced a blunt gorget, passed the forceps along it, and, without further difficulty, completed the operation. These proceedings took much longer than their description would imply. He confessed that, to himself, the minutes seemed hours—the quarter of an hour which the operation required being to him a most anxious one. It was the first time he had ever used a probe-pointed knife in the second step of the operation, and it would be the last. He could not help remembering that in some cases the bladder had not been reached at all—a mischance always fatal. Many explanations had been offered to account for failing to get into the bladder. Mr. Dease thought that the "stop" at the end of the staff had something to do with preventing the knife from getting in, or with taking it out unexpectedly and pre-

maturely. Accordingly he recommended the use of an instrument open at the end—a principle adopted in Dr. M'Donnell's staff. Mr. Peile advised that the operator should hold his own staff, considering that the *consensus* between the two hands was likely to lead to a more ready striking of the groove, and a more certain entrance into the bladder. Dr. M'Donnell also adopted this recommendation, but was believed to be the only operator in this country who did so. The "stop" at the end of the staff could hardly act the dangerous part Mr. Dease assigned to it if the instrument were kept well in the bladder, and, above all, if this important rule were always observed of never—under any circumstances—withdrawing the staff until the finger touched the stone, the only *infallible proof that the bladder had been reached*. Although his personal experience as a lithotomist was limited to a few cases (as stone is a rare disease in Ireland), yet as "lecturer on surgery" he had performed a very large number of operations on the subject from year to year. From what he had observed, he was satisfied that in most cases the failure to reach the bladder resulted from the manner in which the staff was held. The assistant in charge, in his anxiety to watch the steps of the operation, would allow his hand to droop and rest on the abdomen of the patient, thereby drawing the concavity of the instrument's curve round the sub-public structures, and lodging its point in the membranous portion of the urethra. The knife, passed in the usual way, would incise the structures as far as the prostate. The finger introduced, slipping off the end of the staff, would pass under and behind the gland, between it and the lecturer, and would find a loose and dilatible space, but not the bladder. He need not say that accident did not occur in the case under description, as the staff was held by his colleague Prof. Stokes. Another explanation was offered in the case of children. It was suggested that by the use of too much force in introducing the finger, the urethra was torn across and pushed up along the staff to the prostate, which also, as well as the bladder, readily became displaced upwards. He confessed that the latter explanation flashed across his mind when the delay occurred, and made him use the probe for the purpose of ascertaining the position of the staff and the relation to it of the membrane alluded to. That enabled him to make sure that the Blizard's knife would reach the bladder and make the necessary section of the structures complete. That the last explanation was not the true one was happily shown by the result of the operation. In conclusion, in calling for remarks on the case, he would ask the Society to excuse any shortcomings in his description of it, as his bringing it forward was quite unpremeditated, and only, as it were, "to stop a gap" in their proceedings.

Mr. THORNLEY STOKER said the operation of lateral lithotomy in the adult, provided no extraordinary difficulties existed, was a comparatively simple one. In the child, however, a different state of affairs existed. The structures being so soft, offering little resistance to the finger, the tissues so loose, and the relative position of the viscera so different, there was extreme difficulty in introducing the finger along the staff, or whatever guide was selected. The reason Mr. Corley had suggested as affording a difficulty was the most correct one; he probably did not open the urethra sufficiently to permit of his finger passing along the staff rapidly into the bladder. The structures were so exceedingly soft in a child that no force could be employed; and if a free opening was not made into the bladder—a much freer opening, relatively speaking, than into the adult—it must be difficult to pass the finger without lacerating the parts extensively, and worse still, pushing the bladder backwards and upwards. It seemed to him there was one manœuvre that might in such cases be of great use—namely, the assistance the operator could, in this procedure above all others, give himself by taking the staff in his left hand at the time he was endeavouring to pass his finger into the bladder, and instead of keeping it fixed in the middle line of the perineum, if he lifted the body of the staff to the left side of the patient, he would put the opening transversely on the stretch and facilitate the entrance into the bladder. Another point of interest was this, that even when he had got into the bladder, there was some difficulty in finding the stone. At the Pathological Society Mr. Croly had referred to this, and asked the question why it was that when operating for stone in the bladder in children he had found a certain difficulty in seizing it that did not exist in cases of vesical calculus in the adult? It occurred to him that an

explanation might be found in the fact that the bladder in children occupied a different position, and was different in shape, to that in the adult, being an abdominal viscus and situated higher up, so that the stone could get lodged above the pubis.

Mr. O'GRADY was taken aback by the observations of Mr. Stoker. His experience had proved that the difficulty was to get into the bladder of a child and to get the stone out of the adult. He could sympathise with Mr. Corley; for in a case he had had himself some years ago the time occupied appeared like an age. The gentleman who held the staff, in his anxiety to see the operation, leaned over and displaced the staff, so that when he (Mr. O'Grady) cut down he was not in the bladder. Fortunately, having withdrawn the staff, an ordinary catheter went into the bladder. He got the stone, and the patient recovered. But for the assistant letting an accident occur, he could not conceive an operation so simple as the ordinary lateral lithotomy. Having a grooved instrument, if the operator followed it he could not fail to get into the bladder, unless displacement occurred. But displacement had occurred, and in more than one case, and the operator had got blame where he was blameless, the fault being that of the assistant. In an old man of sixty he had had difficulty in getting the stone out, adhering as it did to the pubis, and a strip of bladder came with it.

Mr. THORNLEY STOKER explained that Mr. O'Grady had misunderstood him. He spoke of the difficulty of opening into the bladder of a child being so great that he looked on it as an operation of a different category.

Mr. ORMSBY said he had experienced the same difficulty as had been mentioned in getting into a bladder of a child. In the last case he did not know how long he was, but he removed the stone, and the child got well. If the staff-holder held the staff in its proper position in the bladder there ought not to be very much difficulty in getting along the groove of it. The difficulty Mr. Corley mentioned of getting the finger up behind the prostate, or between it and the rectum, was a likely one; the great point was to strike from below upwards. Another important point was one for which he was indebted to his friend Mr. Porter, and that was to get the finger, not along the convexity of the staff, but along the concavity, as a certain guide into the bladder. Again, it was also important to arrange, if possible, that the child's bladder should be distended.

The CHAIRMAN said a most important point was the size of the staff used. With a staff as large as the urethra would carry there would be little difficulty in getting into the bladder. Mr. Corley had not mentioned the size of the staff he had used. Young operators used small staffs, and, unless they were lucky, the chances were they would bungle the operation.

Mr. CORLEY.—The staff used with the child, *et. 8*, was No. 6.

Mr. WHEELER did not agree with one of the speakers who said that there was no difficulty in getting into the bladder in performing lateral lithotomy, although in all his stone operations he had been fortunate enough not to experience any difficulty, except one, and in that case it was caused by catching the stone, which was large and flat, in the long axis. He did not change his knife for a blunt-pointed one, but continued the operation with the knife he commenced with, taking care to get it well into the groove in the staff. The anatomical differences between the bladder in the adult and the bladder in the child were alluded to in every surgery, and he would not discuss them; but, in his opinion, Mr. Corley's difficulty was, that the urethra of the child was pushed before his knife along the staff.

Mr. BENNETT said Mr. Ormsby had mentioned a point of considerable importance as to the difficulty of following the groove of the staff. Holmes, who did not claim to be a great authority on the subject, insisted, in his *Surgery of Children*, on the importance of overcoming the difficulty of entering the orifice by following the upper surface of the staff instead of the lower. He had himself found that the attempt to follow the groove was a failure, while great facility occurred on shifting the finger to the upper surface of the staff.

Mr. CORLEY replied. The point about holding the staff could not apply in this case, as, being held by his colleague Mr. Stokes, it was held as it ought to be held, which was proved by the fact that he got in afterwards. Dr. McDonnell was in favour of the operator himself holding the staff. But he was not disposed to be converted to it; for while getting the knife

into the urethra, the operator was assisted by having the use of his left forefinger, and it was a simple push that must be made with the knife to get in that way. Mr. Stoker had made a mistake about the difficulty in getting the stone. The moment he got his finger into the bladder he felt the stone, and it was not because it lay above the pubis he found difficulty. Mr. O'Grady and Mr. Ormsby had made some pertinent observations with reference to passing his finger along the concavity of the instrument. That was one of the reflections that passed across his mind; but the urethra having been cut, if he attempted to get his finger in he was afraid he would tear it or push the urethra and bladder into the pelvis of the patient. He thought it better to put a probe in, and make sure what was the obstructive membrane. Mr. Richardson's observation was exceedingly valuable. The largest instrument should be used. He introduced No. 6 staff, which fairly filled the urethra, and there was then the difficulty alluded to by Mr. Ormsby of getting into an empty bladder. With reference to what Mr. Wheeler said of the urethra running before the knife, he could answer at once. He left down the blunt knife, and pushed the sharp one along the groove; so that, at all events, the urethra could not have passed up before the blunt knife.

The Society then adjourned.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

DOUBLE PLACENTA.—At the Académie de Médecine, M. Tarnier presented a double placenta, which was expelled after difficult labour in his service at the Maternité. A quarter of an hour after the expulsion of the fetus, the placenta descended into the vagina and appeared at the vulva. A few slight efforts made by the woman, aided by a little traction, brought it outside, but when the midwife was about to take it away, she found that it was retained by a portion of the membrane. The midwife, according to instructions laid down by M. Tarnier in similar cases, abstained from drawing at the membranes, and applied a ligature. Soon afterwards flooding came on, and with it a supplementary placenta, smaller than the first, and united to it by a sort of membranous bridge. Such was the case, and the question arose as to the possibility of recognising the existence of these accessory placentas before expulsion. After expulsion of the normal placenta, a string of membranes has often been observed lying in the uterus and retaining the membranes of the ovum. This retention is to be, according to M. Tarnier, attributed to three causes—abnormal adherence of the membranes, twisting of the membranes around a clot, which hinders their exit from the uterus, and lastly to the presence of an accessory placenta. A fact that must be borne in mind is that in the two first cases the membranous bridge contains no vessels, while in the last branches of umbilical vessels are to be found in its folds. Thus by examining carefully the membranes outside the vulva, the presence of a supplementary organ may be inferred if sanguineous vessels are found.

TRANSFUSION.—Transfusion is to-day by no means a rare operation, and medical men have fully recognised the legitimacy of expecting favourable results from it when practised under favourable conditions. Those conditions consist in keeping the blood to be injected from coagulating, from cooling, and from the contact of air and the substances it contains. Of all the procedures invented to attain these ends, that of Dr. Roussel (Geneva), merits the preference, in that it has, in his hands, fulfilled all the requirements necessary to the success of the operation. Dr. Roussel, a few days ago, in Paris, performed transfusion, and I have no doubt that a few notes of the case will be read with interest. A woman, *et. 35*, had already five children and two miscarriages. In December last

she was six months pregnant, and suffered a great deal. The abdomen was enormous, and she distinctly felt the movements of the child. Two medical men who examined her, believing that they were in presence of an ovarian cyst, sent the woman to Dr. Peau, the celebrated ovariologist. M. Peau recognised at once pregnancy, and as labour had prematurely set in, the woman refusing to stay in the hospital, was transferred to the house of a midwife, who immediately broke the membranes, giving issue to nearly 20 quarts of amniotic fluid. Twins were successively and easily delivered; one of them lived a couple of hours. The loss of blood was no more than usual, and all appeared to go on well. On the 1st January, the eighth day after the delivery, the woman was seized with flooding, which was apparently arrested by plugging, but, as was afterwards proved, the hæmorrhage still went on in the cavity of the uterus. Ten days afterwards another attack of hæmorrhage occurred, but more serious than the first, and was followed by syncope, convulsive movements, &c. Ergotine and cold aspersions with the horizontal posture mastered it, but the patient was blanched, cold, and affected with cough accompanied by continued fever. The pulse was 130—140, vomiting, frequent diarrhœa, and complete loss of appetite were the other symptoms observed. The patient was attended by four medical men, including M. Peau, who believed that some uterine fibroma was the cause of the hæmorrhage. On the 31st Jan., becoming worse and worse, the woman desired to be brought to her own home. Bismuth, morphine, iron, pepsine inhalations of oxygen, &c. were ordered. The patient, although no new attack of hæmorrhage occurred, became weaker and weaker, the vomiting was frequent, and the diarrhœa came on every hour. The fainting was produced every time she attempted to sit up, the cough became more frequent, and the respiration was insufficient. Death was evidently at hand. At this stage transfusion (direct) was recommended as a last resource. Dr. Roussel, who happened to be staying at the Grand Hotel, was sent for, and on his arrival found the patient in the following state:—Barely conscious, cold, pale as a corpse, veins invisible, pulse 140, and thready. The heart and lungs were healthy. On the 7th of February, and at five in the evening, the patient being in the position above described, with exception of the pulse, which was now 150, the operation was performed. The sister and the husband of the woman offered their arms, but Dr. Roussel, on inspection, refused the offer, and on inquiring if there were not some large workshop in the neighbourhood, hastened to one indicated, and having explained to the workmen the nature of his visit, several came forward ready to give their blood. A young man, small and robust, was chosen. Arriving at the bed-side, the transfusor was washed in warm water to which a little soda was added. The thorax of the patient was uncovered, and the left arm was lying straight down by her side. After having mapped out with ink the course of the artery at the bend of the elbow of the young man, the transfusor was applied over the median vein, the same vessel was opened in the arm of the patient, and the canula of the instrument inserted as soon as all the air was expelled from the transfusor. This was effected by plunging the bell of the instrument in warm water, which, by means of the ball pump, was sucked up so as to completely fill the tube, expelling all the air. The two subjects were now united by an uninterrupted canal, through which the blood was allowed to flow gently. After four ounces were injected, the patient drew a long breath, and on being questioned said that she felt a sensation of warmth going up from the arm to the chest. As soon as six ounces were transfused, the operation was arrested, as a slight convulsive movement was observed in the patient. The wound in the arm of

the man was dressed and he returned to his work. As to the patient, colour was observed in her hitherto blanched cheeks, her lips were red, and her eyes brilliant. She spoke with strength and vivacity. She felt herself strong and well. Dr. Roussel, having warned her that a shivering generally came on (due to the re-establishing of the equilibrium of the vaso-motor system) a short time after the operation, which would be followed by profuse sweating and refreshing sleep, hot tea and rum was held in readiness. In half an hour the shivering came on; the skin, which had been warm, became cold; the pulse, which stood at 100 after the transfusion, now went up to 140. Hot drinks were given in abundance, and after twenty-five minutes the body became more warm, and soon perspiration was abundant. As night came on the patient slept a broken sleep, yet the following morning she felt comparatively well, and during the day was able to partake of nourishment six times, and receive visita. The *bien être* continued, and on the 12th Feb., or five days after the operation, the woman got up for an hour or two, and to-day, the 25th Feb., the convalescence is complete. Dr. Roussel, who has already practised 128 transfusions, comes to the following conclusions:—1. Injection into the veins of a liquid other than blood is followed rarely with good results. 2. Transfusion of the blood of an animal of a different kind is always hurtful. 3. Transfusion of the blood of the same kind by the indirect method is very often unsuccessful. 4. Transfusion to succeed must be direct.

Department of Lunacy.

EDINBURGH ASYLUM FOR THE INSANE, MORNINGSIDE.

THE annual meeting of the subscribers to this institution was held in the Council Chamber, Edinburgh, on Thursday last, Sir Alexander Grant presiding. Mr. Scott Moncrieff read the managers' report, in which it was stated that the income for the year amounted to £45,775, and the expenditure to £46,869, leaving a balance against the institution of £1,094. On the motion of the Chairman, seconded by Mr. Charles Cowan, the report was adopted. After the election of new managers, Dr. Clouston, Superintendent of the Asylum, read his report, from which it appeared that during the year 339 patients had been received, of whom 162 were males and 177 females. There were in all 1,160 patients in the asylum during the year. Of the 273 discharged, 118 were men and 155 women, and there had been 67 deaths—40 men and 27 women. The admissions were 13 less than the average of the five preceding years; and there was a diminution in the number of private patients, accounted for by more beds being taken up for pauper cases. They had about 90 re-admissions; and in connection with that subject he might say that periodicity in insanity was a law as fixed as the east wind or the average rainfall of a district. He had bestowed much attention on the subject, and believed that the longer these periodic occurrences of insanity prevailed, the longer the periods tended to become. Speaking of the dietary, he said that while not altogether overlooking the advantages of stimulants, he had latterly used milk very largely. One patient was given eight pints of milk and sixteen eggs daily in addition to his ordinary diet. Without this and fresh air he could not have lived,

but he was now recovered, and was performing the duties of his position as well as he ever did in his life. An accompaniment of all mental diseases was a wasting of the body, and he constantly preached to his nurses the gospel of fatness. More had been paid for cod-liver oil than for any other medicine. Of the 273 discharged, 162, or 48 per cent., were cured; while for the whole of Scotland the average was 41 per cent. cured. The walls of the Asylum had recently been covered with bright colours, and he regarded the dark olive greens, so popular with persons of æsthetic tastes, as a device of the evil one, "who loved darkness rather than light." (Laughter.) The report was approved, and after some formal business had been transacted, the proceedings terminated.

THE STAFFORD COUNTY LUNATIC ASYLUM.

THE Annual Report of the Stafford County Lunatic Asylum, in the neighbourhood of Lichfield, shows that of 554 inmates resident there at the time of the visit of the Commissioners in Lunacy, 150 were subject to epilepsy, and 28 were labouring under general paralysis of the insane. The health of the patients was fairly good during 1881, and neither seclusion nor restraint were resorted to. Various improvements in the institution are ascribed to the zeal and energy of Dr. Beveridge Spence, who succeeded Dr. Davis in the office of Medical Superintendent in the beginning of last year. Protection against fire has been provided by the fixing of new internal hydrants in proper positions throughout the Asylum, and also of external hydrants with adequate lengths of hose. A good manual fire-engine has been purchased, and Tozer's hand-pumps have been added to the means always ready for the extinction of fire. A fire brigade has been organised and drilled, proper rules and instructions how to act in an emergency have been printed and distributed among the nurses and attendants, and regular practices with the various appliances have been ordered from time to time. The sewerage from the Asylum is now applied direct to the land by means of carriers cut out of the soil; this plan has been found to work well and has done away with the nuisance created by the decomposition of sewerage matter in a large open pit, besides permitting of a wider area of irrigation than was formerly possible. A portion of the storm water has been diverted from the main drain and carried off in another direction, but sufficient still goes by the old channel to flush the drains out thoroughly after heavy rain. Dr. Spence refers to the necessity of having a reference plan of all the drains of the Asylum and of the position of all steam and water pipes. No asylum nor hospital should be without such a plan always well brought up to date.

THE NEWCASTLE-UPON-TYNE LUNATIC ASYLUM.

THE demand for accommodation in the Newcastle-upon-Tyne Lunatic Asylum, and especially in the female wards, has led Mr. Wickham, the medical superintendent, to give every encouragement to relatives to remove patients who, although not recovered, are yet sufficiently improved to warrant such a step. The responsibility entailed in carry-

ing out a system of this kind is considerable, but Mr. Wickham has no doubt that much good is done, and much happiness secured by it. Every one with experience of the insane knows that there are certain patients who, though obviously of disordered intellect, have learned to conceal delusions and other symptoms sufficiently to prevent them from being dangerous to the public peace, and when such patients have judicious relatives with leisure enough to look after them properly, a sojourn with them, if it be only for a few months, is likely to be highly appreciated. Not a little firmness is required in resisting the importunity of patients who are not suitable cases for such treatment. It is difficult for them to believe that a man who is quiet and orderly, and industrious while in an asylum, will not be the same outside; but so it is in fact, as is often apparent when a medical superintendent, following inclination rather than judgment, permits a patient to be improperly discharged. The Asylum contained 264 patients—131 males, and 133 females, at the close of last year.

REGISTERED FOR TRANSMISSION ABROAD.

THE
MEDICAL PRESS AND CIRCULAR
Is published every Wednesday morning. Price 5d. Post free, 5½d.
POST FREE TO ANNUAL SUBSCRIBERS £1 2 6
" " IF PAID IN ADVANCE 1 1

* Post-office Orders and Cheques to be drawn in favour of—
A. A. TINDALL, 20 King William Street, Strand, London, W.C.
A. H. JACOB, 3 Molesworth Street, Dublin.

Agents for Scotland:—

MACLAUGHLAN and STEWART, South Bridge, Edinburgh.
A. and W. STENHOUSE, Hillhead, Glasgow.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 3s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILLMER and ROGERS; Philadelphia, by Dr. BRINTON, post free in advance, 5½ dollars (£1 3s. 6d.) per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order

ADVERTISEMENT SCALE.—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.

Small Announcements of Practices, Assistances, Vacancies, Books, &c., of Seven lines or under, 4s. per insertion; 6d. per line beyond. Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

WEDNESDAY, MARCH 8, 1882.

THE NOTIFICATION OF INFECTIOUS DISEASES.

THIS question is in a state of block in the House of Commons. Mr. Meldon's Bill is stopped by Mr. Gray, M.P. who has introduced his own Bill of last year, to force physicians to notify to the sanitary authority. Mr. Gray's object is, we believe, not so much to pass his own Bill, which he must know is hopeless, but to force Mr. Meldon's Bill into a select committee, where he well knows that the profession concerned would have but a

slender chance of success. Mr. Gray is, of course, the best judge whether no Bill at all, or Mr. Meldon's Bill is the preferable alternative, but, it seems to us, that in refusing to allow a reasonable practical measure to pass, which satisfies all parties, he is playing effectually the game of those who resist notification in any form, and is not in any way thwarting the doctors, who are willing and anxious for notification, but certainly will not accept it on the terms which Mr. Gray offers them. We hope that all steps necessary to prevent Mr. Gray's Bill getting a second reading will be immediately taken, but we may have to re-open the campaign against his Bill which gave the Irish Medical Association and ourselves so much trouble last year.

Besides the opposition of Mr. Gray and the compulsionists, there is that of Mr. Thomassen, M.P. for Bolton, who has blocked all the Bills on the subject, including Mr. Hastings' English measure. The honourable gentleman represents a knot of Radical fanatics, who go for "the liberty of the subject" to disseminate small-pox and syphilis, nurture cess-pools, or do anything else they please, no matter how mischievous. These people call themselves "The Vigilance Committee for the Protection of Personal Rights," and have as their Parliamentary exponents Mr. P. Taylor, Mr. Hopwood, and Mr. Thomassen. Their opposition once the Bill comes before the House is insignificant, but they can and do obstruct. It is, however, gratifying to know that the profession is at length aroused to the necessity for protecting itself. The King and Queen's College of Physicians in Ireland adopted last week the following resolution, upon the bringing up of the Report of Parliamentary Bills Committee, which recommended the College to support the Infectious Diseases Notification Bill (Ireland), introduced into Parliament by Mr. Meldon:—

Resolved (unanimously)—"That the Report of the Parliamentary Committee be adopted, and that they be instructed to support the Bill for the Notification of Infectious Diseases introduced by Mr. Meldon and others; and also to take steps to oppose or amend, in accordance with the views of the College, the Bill on the same subject introduced by Mr. Gray."

The matter has also been taken up by the *Students' Journal and Hospital Gazette*, which, in its last issue, writes as follows:—

"An attempt is being made to render it compulsory upon medical men to notify to the parochial authorities all cases of infectious diseases that come under their observation. If this should become law it will be one of the severest blows ever struck at the profession, and we are glad to see that medical men in the larger towns are taking up the question and organising opposition to the proposition. An important meeting was recently held at Manchester to consider the question. A resolution was proposed condemning the proposal to compel medical men to make notification of every case of infectious disease to the sanitary authority, as an unwise and unwarrantable interference with the relations between such medical practitioners and their private patients, and declaring that the dread of publicity might lead to the concealment of the disease. The opinion of the meeting generally was against the throwing of the responsibility of notifying disease on the medical men, and, after a long discussion, the resolution, amended so as to declare that the compulsory notification of infectious disease is of great public and national importance, but that the responsibility of

notification should rest on the householder, was agreed to. We understand that a meeting of the profession to take the subject into consideration will shortly take place in London, under the auspices of the British Medical Association. Every medical man should come forward and offer the most determined opposition to the attempt to saddle him with the unpleasant duty of reporting the condition of his patients to parochial authorities."

THE PROPOSED ACADEMY OF MEDICINE OF IRELAND.

We referred some weeks ago to a proposition which was engaging the attention of the Dublin Pathological Society for amalgamating the four societies in Dublin which now represent Medicine, Surgery, Pathology, and Obstetricity. This proposal has now assumed the form of a draft scheme, which has been worked out by a sub-committee and submitted for consideration to the four societies whose co-operation is desired. We append an abstract of the important portions of this scheme:—

The name of the new Society is to be "The Academy of Medicine in Ireland." It will consist of four sections, corresponding to the four societies now existing, and will be managed by a General Council, consisting of President of the Academy, the Vice-Presidents of Sections, and twenty Councillors selected from the Councils of Sections.

All members of the existing Societies, and all Fellows of the Colleges of Physicians and Surgeons shall be members of the Academy without ballot, the former class being exempt from entrance fee. All other candidates for membership shall be balloted for by the General Council, one bean in four to reject.

Members shall be privileged to attend, speak, and vote at all meetings of the Academy or its Sections, and will receive a copy of the Transactions free. Associates, who must be registered practitioners, shall be elected on same terms as members. They may attend and speak at meetings, but not vote, and they can buy the Transactions at cost price. Student Associates may also be elected in same manner, and may attend meetings.

The fees will be, for members, £2 2s.; for Associates, £1 1s.; for students, 5s. After original members have joined, all others will be charged £1 1s. entrance fee.

The General Council will meet monthly, and extraordinary meetings can be called by requisition. The Sectional Councils shall consist of a President, Vice-President, and five Members elected at the Annual General Meeting of the Academy. One member of each such Council shall retire annually, and not be re-elected for two years.

The executive officers of the General Council shall be Honorary Secretary, Treasurer, and Honorary Secretary for Foreign Correspondence.

The communications to be submitted to the ordinary meetings shall be grouped under the following heads:—Medical, Surgical, Pathological, and Obstetrical; and the conduct of such meetings shall be in the hands of the several Sectional Councils, each Sectional Council to have the management of the ordinary meetings in regular rotation. The Council of the Pathological Section to have charge of the first in each Session; that of the Surgical of the second; that of the Medical of the third; and that of the Obstetrical of the fourth; and so on until the end of the Session.

The ordinary meetings shall be held on every Friday evening from November until May, inclusive, except during the recesses.

The place of meeting of the Academy is stated in the scheme to be "such place as the Council may provide," but it is suggested that the meetings shall take place alternately at the Colleges of Physicians and Surgeons.

The Transactions of the Academy are to be printed as a yearly volume, and are to contain such communications as the Council "deem suitable for publication."

This scheme is, we believe, generally regarded with approval by the profession in Dublin, and we think, from the public point of view, deserves that approval, though it is questionable whether it may prove beneficial to some of the societies concerned.

The three points in the scheme which seem to us most deserving of special consideration are the amount of the subscription, the place of meeting, and the method of publication of the Transactions. As to the rate of subscription, it seems to us that an entrance fee of £1 1s., and an annual subscription of £2 2s., may possibly be a deterrent in the case of the humbler practitioners, although it may not be excessive when the publication expenditure of the Academy is considered. The money question will, however, influence the societies in their decision as to whether or not they will co-operate, because their existing financial arrangements differ very materially. The Pathological and Obstetrical Societies cost £1 1s. a year; the Medical Society, 5s.; and the Surgical Society, nothing, save the small sum contributed by each member for refreshments. Thus the members of the latter two societies will be called upon to pay £3 2s. annually, and it is probable that the roll of members will show a material falling off if such a demand be made.

The place of meeting and the constitution of the first Council are important only because of the danger that these points may be settled in such a way as to give the Academy a one-sided constitution. It would be altogether fatal to the success of the scheme if it were tinged with the special colour of any college or any society. The Academy, if not cosmopolitan, has no claim to exist at all, and we hope that—if the scheme meets with preliminary approval—every vigilance will be exercised to keep it free from medical sectarianism. The *raison d'être* of the Academy seems to be the publication of its Transactions. Heretofore, none of the four Societies, save the Surgical, have enjoyed the advantage of speedy and widespread publicity of their Transactions. Papers have been read, and specimens exhibited in the privacy of the Society's meetings, and have been thenceforth buried out of sight until they were partially exhumed a month or two afterwards, and—after a period of second sepulture—embalmed and consigned to ultimate oblivion in volumes of Transactions which no one ever read and few ever saw. Naturally and inevitably these Societies have languished. How could it be expected that authors would expend their energies on papers laboriously worked out for the benefit of a dozen or twenty hearers, and the possible advantage of a few book-worms of the future? We say, therefore, that if the finances and scientific work of the Academy are to be swallowed up in a pretentious volume of unregarded "Proceedings," the scheme is not worthy of support, and, if successfully inaugurated, will certainly eventually fail. There is only one safe and liberal course in this matter, and that is, a declaration of free trade.

All journals should be privileged to report and publish any portion or the whole of the proceedings of any

or all the Sections. For those journals who do not take a special report, a sufficient abstract of the proceedings of each meeting should be prepared *immediately after the meeting* by a publication committee, and forwarded by them by the same post to every journal which wishes to receive such report. Finally, the papers and discussions *in extenso* should be published for permanent record in the volume of Transactions of the Academy.

Subject to these considerations, we think the project for an Irish Academy of Medicine ought to be welcomed, and will succeed, and we, in the interest of the Irish school of medicine, wish it prosperity. Free interchange of thought and experience, and free co-operation amongst members of the profession in all specialities must prove beneficial, not only to science, but to those who are joined together for the purpose, and we think a well devised and liberally interpreted scheme having such an object ought to succeed.

OUR PROVINCIAL MEDICAL SOCIETIES.

WE believe there are a large number of provincial medical societies, but we very seldom read or hear of their transactions. They are not silent, we know; they have meetings, papers are read, discussions take place. There are no reporters present, so that valuable papers are, to a certain extent, lost to the medical world. When we consider the vast stock of material at the command of the general practitioner, we regret that so much of it runs to waste; some of it must be worth publishing. The London, Dublin, and Edinburgh societies have every facility for the publication of their proceedings; the provincial societies can follow suit. At one of the London societies the treatment of rheumatism has formed the subject of discussion. The general practitioner should have something to say on such a topic. It would be well worth the attention of some of those societies to start a discussion on the subject, on their own data. Puerperal fever is another interesting topic. It is important to the general practitioner. Midwifery is the key-stone of provincial success. Without a good midwifery practice the general practitioner cannot succeed. It is the Open Sesame; it secures him attendance on the whole household. Can he attend other cases when he has had a case of puerperal fever in his practice? What does he do in such an emergency? What are the statistics on the prevalence of puerperal fever in the provinces? We could fill up pages of questions on this disease. We could suggest a variety of interesting points for debate, but we have, some months back, alluded to this subject, so that we need not now repeat our arguments in favour of discussion by such societies of moot points in medicine or surgery. There is, we believe, a certain amount of diffidence on the part of provincial practitioners in sending papers for publication; and there is also a feeling that writing for the press is injurious to success—patients may be apt to think that the man who writes has not much practice, if he had very much to do he would not have time to write. Some narrow-minded medical men foster this preposterous idea, it is to their interest to do so. There are many provincial men who write well, and who have proved notable exceptions to the general rule. The time is coming when the general

practitioner will write more. The fierce light of education is beating down old prejudices, old customs and habits are disappearing. This fallacy is nearly exploded. In France provincial surgeons have facilities, by means of local medical papers, of exchanging ideas, hence the art of composition is more cultivated. In England there is only the metropolitan medical press to fall back on. We can assure our provincial *confrères* that we shall have pleasure in receiving their communications, and that any interesting debate will receive as much space as we give to the metropolitan societies.

Notes on Current Topics.

Law and Physic.

It is an old proverb that doctors differ and patients die; and from time immemorial the public have been in the habit of amusing themselves at the expense of a profession of which, however, the moment they get ill, all hasten to take advantage. In health many persons think Molière's *Médecin malgré lui* is a very entertaining composition; but should pain or danger of life occur, these very individuals are the strongest in their belief in medical infallibility. No class of men are more apt to deride physicians than our legal brethren; especially if before an intelligent jury they get the chance of laying the oratorical shillelagh upon some medical witness who may have had the misfortune to give evidence adverse to whichever brief they happen to be paid for. We think that after the Guiteau trial the lawyers may think of setting their own house in order. The moral sense of the world would have been shocked at the spectacle of a vulgar commonplace ruffian who, in a public railway saloon, publicly shot the chief magistrate of the United States, in the presence of a Cabinet minister and a number of spectators. Taken in the very fact, with his smoking pistol in hand, it would be thought that his shrift would be short. But short shrifts do not pay the gentlemen of the long robe, and, accordingly, day after day and week after week was the legal farce prolonged. The defence that the President's death was caused by surgical incompetence was too audacious (as yet) even for American lawyers. The illustrious patient was attended by the first surgeons of America; and the pathological investigation justified both diagnosis and treatment. Insanity was the only plea, and this was pushed *usque ad nauseam*, and effectually upset by the behaviour of the prisoner in the dock, who exhibited all the cunning of a low attorney, and not the faintest sign of mental aberration. Everything must come to an end, and at last Guiteau was found guilty; a new trial was refused; *et finis coronabit opus*. Even here the extraordinary course was pursued of postponing the execution for half a year, and money is being freely laid on the other side of the herring pond that the criminal will not be executed at all.

The most repulsive aspect of this nauseous business is the sickly sensationalism displayed by the American public. During the whole trial the pages of our American contemporary *Frank Leslie's Illustrated Journal* have been

filled with the scenes of the trial, portraits of the prisoner, pictures of him at exercise, at meals, *et alia talia*. The latest of these in the last number represents the closing scene in court, with a crowd of well-dressed persons, mostly ladies, eagerly hustling each other at the dock, and thrusting papers and pencils into Guiteau's hand for the purpose of obtaining his autograph. We understand that all his personal belongings, even to his own body, have been converted by the convict into cash, and at a high figure; and we learn that he has issued an appeal for money, which is very liberally responded to. We should have thought that money would be as useless to him now as the Spanish gold which Robinson Crusoe found upon the wreck, which he wisely said he would give for a box of tobacco pipes; but it appears it is not so. The whole story shows a profoundly unhealthy state of the public mind, and we fear that nothing short of some great moral thunderstorm will clear this vitiated psychological atmosphere.

The Dental Diploma Trade.

THE *Students' Journal and Hospital Gazette* publishes in its last issue a leading article on this subject. It says:—“The *Medical Press and Circular* has recently done good service to the profession by directing attention to the scandalous trade which is being carried on in the sale of dental diplomas by the three surgical corporations which have their headquarters at Edinburgh, Glasgow, and Dublin. Cases have come under our notice of persons obtaining the diploma who previously made no pretence whatever to have practised as dentists. For instance, two of the first persons to obtain these diplomas were two men, who for years past have practised as quack doctors, and both have been prosecuted for unqualified practice by the Medical Defence Association; one of them having been twice convicted and fined very heavily on both occasions. The other was fortunate enough to escape conviction, through some legal technicality, and he still pursues his trade as a ‘spermatorrhœa quack,’ and his disgusting pamphlets are distributed in the streets of London daily. We believe we shall not be contradicted when we state that these two worthies *certified to each other's fitness* to hold the dental diploma, and that the Irish College of Surgeons granted them their pieces of parchment without curriculum. We hear that the name of the ‘spermatorrhœa quack’ has since been removed from the Register. The other individual keeps an open surgery and chemist's shop, and although he describes himself as a dental surgeon, we never heard of his doing any dental work, but we know that he does a large prescribing business in medical and surgical cases, and is commonly believed to be a duly qualified surgeon, as he has his name painted in large letters on his window, followed by the mysterious title ‘L.D.S. Royal College of Surgeons.’”

THE health of that favourite watering-place, Hastings, continues most satisfactory. From the last quarterly report of the medical officer of health to hand, we learn that the death-rate is only 15 per 1,000 of the population, including visitors, who are frequently sent there in the last stages of consumption.

Professional Consultation by "Suspects."

MR. REDMOND asked the Chief Secretary if it was a fact that on the 18th of January last a lady and a gentleman made application to pay a professional visit to Kilmainham to Dr. Joseph Cardiff, who for twenty years had been their medical attendant, and whether such application had been refused; and that eventually the visit had to take place in the ordinary cage, and in the presence of two warders, and was useless from a professional point of view? Mr. Forster said the authorities had decided to allow the visit, and under the circumstances he considered them right in having done so.

Lunacy in England.

THE number of lunatics, idiots, and persons of unsound mind, detained in workhouses in England and Wales, on January 1, 1881, was 16,811—an increase of 347 on the number so detained on the corresponding day of the previous year. Of this number, however, 4,718 were inmates of the Metropolitan District Asylums, which are in the legal position of workhouses within the meaning of the Lunacy Acts; so that 12,093 lunatics or weak-minded persons were detained in workhouses proper.

The Attempt to Assassinate the Queen.

THE dastardly attempt to take the life of the Queen, but from which Her Majesty so happily escaped without serious consequences, has naturally excited the profoundest feelings of horror and detestation throughout the civilised world, while at the same time the most heartfelt thankfulness is experienced at the utter failure of the attack. It is satisfactory also to be assured that the proceeding is wholly unassociated with political motives, since recent events are not entirely without significance in such a connection. Frequently as Her Majesty has been the object of a would-be assassin's aim, we have every reason for separating the perpetrators of the outrages from that class of disaffected persons which has for its object the despatch of an unpopular monarch. The Queen of England can never be regarded in this light, the whole body of her subjects being united in a loyal wish for her continued welfare and safety; and hence it is that no surprise is felt at revelations which prove the insanity of the miserable creature who last sought the life of Her Majesty. Criminal in the worst possible sense, MacLean is nevertheless widely removed from regicides who are influenced by such passions [as find birth beneath a despot's rule. There is nothing in the act of which he has been guilty that will not find adequate explanation in his antecedent history; deplorable though it is, and must be, it yet is most suggestive as a reproof of the hasty manner in which the mentally unsound are too frequently released from the wholesome confinement of asylums, and permitted to wander at large to the danger of public safety. Even a vulgar craving for notoriety can hardly be accepted as the prime motive in this case, as it undoubtedly was with Guiteau. MacLean strikes us rather as a poor-starved man of weak intellect and morbid ideas; and his act is but a logical outcome of the conditions under which he existed. We cannot pity him, because of the enormity of the crime he

committed, and because its successful issue would have brought grief to every heart. Gladness at the Queen's escape for the time overpowers all other sentiments; but by-and-by we may see in the attempt a lesson that cannot be too earnestly committed to mind, and that should guide us in our treatment of such unfortunates as the perpetrator of this deed.

"A Mere Nothing."

How many people are there whose life-work has been abruptly cut short by the progress of disease originating in the most trivial manner, and unregarded until it has become, perhaps, incurable? A trifling cold; a little pain; a slight indigestion; "a mere nothing," as it is popularly termed, is permitted to exist unheeded for a time, and at length it develops the beginnings of chronic affections, that terminate only with the life of the sufferer. The briefest review of any ordinary practitioner's case-book will supply numberless examples of the kind; the experience of every physician will yield innumerable instances of fatalities brought about by neglect of minor ailments at the outset. Among professional men, and hard-workers in every calling, it is regarded as involving too considerable a loss of time to give any heed to sicknesses that do not entirely incapacitate for discharge of business; and thus to "lie up" for a cold, or for a pain which can be borne with under any possibility, is considered as uncalled-for indulgence. It may be, perhaps, that medicine itself is to blame for this indifference to risk. Too little has yet been made clear respecting the early progress of even dangerous diseases; we are, in spite of all advances, all but absolutely ignorant of the subjective and objective symptoms indicative of the initial lesions which give rise to most dangerous consequences; the "mere nothings" of every-day life may have a significance, and doubtless do possess an importance which, could we but trace the whole evils to which they give rise, would obtain for them an attention they have never yet received. In the absence of this knowledge, it is our duty to impress, at all, times and in all places, the gravity of "trifles," and to stimulate a universal desire to be rid of the "mere nothings" which go far to create the common diseases of mankind.

The Abuse of Red Tickets in Irish Dispensary Practice.

THE Irish Medical Association has, we are glad to say, been successful in establishing an important legal precedent. The support of the Association was promised to a dispensary medical officer in the event of his taking legal proceedings to recover from the issuer of a red ticket, subsequently cancelled, the amount of his fees; and the Council report that the amount claimed was recovered from the ticket issuer. The following is a brief report of the facts of the case, viz. :—

"Claremorris Quarter Sessions. O'Rorke v. Monahan. —Dr. O'Rorke, medical officer of Ballinrobe dispensary district, sued Mr. Monahan for £1 ls., for one visit paid to a patient on a visiting ticket issued by defendant; also for 10s. 6d. for advice given to a patient at the dispensary on a black ticket issued by defendant. In both instances the patients were held by the committee of management of the dispensary district not to be fit per-

sions to receive dispensary medical relief, and the tickets were cancelled.

"The defence was that the defendant did not know for whom he had issued the tickets or the circumstances of the patients, but thought both tickets had been obtained by children. The judge said that the issuer was guilty of carelessness, and that the system being liable to such abuse, he would give a decree for the amount claimed against defendant, as the person who called in the doctor was liable for the payment of his fee, and defendant was the person in these instances who had demanded the medical officer's services. No appeal against the decision was made."

This case is very important, as it establishes the precedent of liability on the part of a ticket issuer for having improperly exercised his privilege. In former reports numerous instances of decrees against the recipients of medical relief are recorded, but this is the first case of a decree against a ticket issuer.

St. Bartholomew's Hospital.

WE are glad to be able to announce that the posts of surgeon and assistant-surgeon to St. Bartholomew's Hospital, created by the alterations recently introduced, have been filled by the appointment of Mr. Marrant Baker and Mr. W. H. Cripps respectively. The elections took place on Thursday last, and will be generally approved throughout the profession by all who take an interest in the fortunes of St. Bartholomew's. Mr. Cripps' candidature was unopposed. This gentleman is likewise surgeon to the Great Northern Hospital, and by his work on "Cancer of the Rectum," to which the Jacksonian prize was awarded in 1876 he has established a reputation for able and original work. In the last volumes of the Pathological Society's "Transactions" Mr. Cripps has published additional observations on the same subject, made since the essay originally appeared.

The election of a fifth assistant-surgeon to St. Bartholomew's Hospital will take place on March 25, and the contest will be a strong one.

Fees for Evidence at Sanitary Prosecutions.

THE Council of the Irish Medical Association reports another instance of successful legal proceedings in the case of a consulting sanitary officer, who, upon the requisition of the sanitary authority, attended at court to give evidence in a case of sanitary prosecution on three days, and claimed £3 3s. remuneration, the sanitary authority declining to give more than £1 1s.

At the instance of this Association, the consulting sanitary officer sued the sanitary authority, and recovered the amount of remuneration prescribed by sealed order of the Local Government Board, viz., one guinea a day for his services.

The £3 3s. thus recovered are to be handed to the Royal Medical Benevolent Fund Society of Ireland, in accordance with the offer made by the consulting sanitary officer at the commencement of the correspondence.

THE Gulstonian Lectures will be continued at the Royal College of Physicians of London on March 8 (to-day) and 10, at 5 o'clock, by W. Ewart, Esq., M.B., the subject being "Pulmonary Cavities: their Origin, Growth, and Repair."

A Curious Accident.

A CURIOUS case is recorded in the *New York Medical Record*, in which a drainage tube, seven inches long, had slipped into the chest of a boy five years old, and who had been treated for empyema. The tube remained in its unusual situation for two weeks, constant coughing being set up by its presence. It could not be fished out by forceps or any other means, and eventually an inch of the ninth rib was excised to facilitate extraction. The tube was improperly fastened; with suitable precaution such accidents ought not to be possible.

Verdict against an Irish Board of Guardians.

AN inquest was held last week in Waterford, in which, after a prolonged investigation, the jury found that the deceased died on the 24th inst. from diphtheria; they believed that the unsanitary condition of the road was calculated to create that disease, several persons having died there from it; and they censured the rural sanitary authority for the bad state in which they had left the district—notwithstanding the reports of their own officer; and they also censured the county surveyor for his neglect of the road, notwithstanding the several applications made by the ratepayers.

The Paris Academie de Medecine.

A SHARP contest has just taken place in this body to fill a vacancy in its list of "free associates," or honorary members, among whom are placed the illustrious names of Prof. Pasteur, Chevreuil, and Milne-Edwards. The committee appointed to examine into the claims of the various candidates declined their classification in order of merit, and returned a list in alphabetical order—viz., MM. Foville, Krishaber, Magitot, Mesnet, De Ranse, and Worms. There was a large attendance of Academicians, and the ballot had to be taken thrice before the necessary majority could be obtained, the contest lying between MM. Mesnet and Worms. Finally, of the 92 votes, M. Mesnet obtained 56, and M. Worms 33, three remaining blank.

The Royal Medical Society, Edinburgh.

THIS Society, older than the Royal Society of Edinburgh by 40 years, held its annual dinner last week, under the presidency of Dr. R. M. Johnston, the senior President of the Society, who delivered an excellent speech on the occasion, in which he stated that the Society had existed and flourished for nearly 150 years, during which time nearly every name of eminence in medicine had been connected with it, and of the many members scattered throughout the world, there was not one that would not bear testimony to the benefits he had derived from the Society, and to the good it did. It appears from Dr. Johnston's further remarks that certain not altogether judicious changes have been made in the laws of the Society, and we hope that his warning to members to recollect how easy it was to destroy an old institution, and how impossible, in many cases, to restore it, will not be lost on the younger members of the Society, who seem smitten by the radical spirit of the age. To all Edinburgh men the traditions of the Royal Medical are very dear, in fact, the meetings of the Society form the one bright re-

collection in the minds of many old Edinburgh students, for if the most anti-social of students wished to select a resting-place, Edinburgh can offer him all the advantages he seeks. We wish the Royal Medical Society God speed.

The Fothergillian Gold Medallist.

A FEW weeks since we had occasion to congratulate our esteemed contributor, Mr. T. M. Dolan, F.R.C.S., of Halifax, on receiving the first prize of £100 over 165 competitors for his essay on "Life Assurance." We have now a further honour to chronicle, namely, the award to him by the Council of the Medical Society of London of the Fothergillian Gold Medal for his essay on "Whooping-cough, its Pathology and Treatment." Pecuniarily, this latter distinction is not of such moment as the former; but, professionally, and as an evidence of more solid and lasting achievement, it is immeasurably superior. As a constant contributor to these pages for many years past, the essayist's name will be well known, and we are sure that many of our provincial readers especially will join with us their congratulations that the honour has fallen at last upon a country practitioner. The medal will be presented this (Wednesday) evening, according to custom, at the annual dinner of the Medical Society of London.

The Money Cost of a High Death-Rate.

THE London correspondent of the *Boston Medical Journal*, reviewing the statistics issued by the English Registrar-General, observes that speaking generally, the death-rate of the country remained stationary from 1840 to 1870, but that in the period 1871-80 it fell from 22.5 (of the previous decade) to 21.5, a reduction equivalent to nearly four and one-half per cent. It may, therefore, be roughly estimated that about a quarter of a million of persons were saved from death in the ten years, 1871-80, who would have died if the death-rate had been the same as in the previous thirty years.

Comparing, then, 1861-70 with 1871-80, that of the entire reduction of 1.0 in the death-rate, more than three-quarters comes under the head of "seven zymotic (infectious) diseases;" of the diseases, that is, which are most influenced by sanitary improvements, and most amenable to control by the action of sanitary authorities.

The pecuniary gain may be thus stated: Under the inquiry as to interments, the cost of funerals—all round—was ascertained to be £5 each. The gain under that head will, therefore, be about one million by the quarter of a million of funerals saved during the last decade. The direct cost of sickness has been estimated at about £1 per case. The gain under that head during the decade will, therefore, amount to about three millions.

DR. LAWSON TAIT, the well-known obstetric surgeon of Birmingham, visited Dublin recently, and read a most interesting and important communication before the Surgical Society of Ireland upon the bearing of antisepticism upon abdominal surgery, he being of opinion that results could be obtained as satisfactory without Listerism as with it. We shall publish the communication in a week or two.

Hoang-Nan, a New Remedy for Hydrophobia.

At a meeting of the Medical Society of the Paris Hospitals, 27th Jan., 1882, M. Gingeot read an interesting paper on the treatment of hydrophobia by Hoang-Nan, a medicament used in the East for various incurable diseases.

M. Gingeot followed the treatment laid down by Pèrr Leceteur, the introducer of this drug. He prescribes pilules of 0.10 centigrammes. The patient took food which he vomited almost immediately. He then subcutaneously injected some of the medicine. The patient died.

M. Gingeot considered that his want of success should not discourage another trial of this drug. In the discussion which followed, M. Dujardin Beaumetz observed that during the year 1881, twenty-three deaths had taken place from hydrophobia in Paris. The most diverse, methods of treatment had been adopted in these cases.

Beaumetz thought that the Russian bath and the administration of garlic was the best treatment. Valdivine, alkaloid of valdavia, a substance employed in Colombia, had been tried. It formed the subject of some experiments made at Alfort on dogs. This remedy was given not to cure rabies, but to prevent it.

The result of this discussion leaves the subject of hydrophobia in the same position as it was before. Another new remedy, another failure.

The treatment of hydrophobia will never be placed on a rational basis until we have some systematic scheme devised, under the supervision of experts, and cases treated in accordance with the principles laid down in our pages in 1877.

We should very much like to know whether the College of Physicians intend publishing the prize essay of Mr. Bourell (Paris), who obtained the £100 given by Mr. Bennett Stanford? If the essay fulfilled the conditions, it is a matter of regret that it should so long have been kept back from the profession.

The Dangers of Pelvic Presentations.

PROFESSOR SPATH, in a clinical lecture on the above subject (*Wien. Med. Zeitung*, Feb. 1882), after speaking of the frequency of their occurrence and of the manifest danger to foetal life from compression of the cord, goes on to say that, according to observations that agree on the point, a compression of the umbilicus of five minutes duration is the longest that can be endured without special injurious effects. Female children are less liable to injury than male. There is a second danger in compression of the cord, viz., in the excitation of respiratory movements in the child, and the consequent inspiration of liquor amnii. This cannot be again expelled from the bronchi, and even if the child should live for the time, it generally succumbs to pneumonia. It is true that all children do not make premature inspiratory movements when the cord is compressed, but where they do, a lethal termination is always, directly or indirectly, the result. Further disagreeable consequences of pelvic presentations are early rupture of the membranes, and freeing of the arms, as when the latter are held back behind the head. In such a case

fracture of the humerus may easily take place, even in the hands of distinguished obstetricians, as happened indeed to the celebrated Martin at the birth of a northern Crown Prince. The children born when the pelvis presents, are generally anæmic, and the reason for this lies in the fact that the umbilical arteries conveying the blood from the child's body are not compressed until the umbilical vein with its thinner walls has already been so for some time.

Eclampsia.

THE same professor reports the case of a patient who suffered from convulsions, partly clonic and partly tonic, with unconsciousness (eclampsia), that ceased shortly before the birth of the child. The professor mentioned the case as one of extreme rarity. As a rule the attacks continue to the end of the labour, or after. As to the origin of eclampsia, hazy views still prevail in the minds of obstetricians. Lever believed it was caused by the over-abundant separation of albumen in the urine. This cannot be so, for many cases of eclampsia occur in which no trace of albumen can be found. Ferich's view is, that urea retained in the blood may produce carbonate of ammonia, and that convulsions and loss of consciousness may result therefrom. Finally, according to Traube-Rosenstein, the blood becomes hydræmic and prone to serous transudation in consequence of loss of albumen: if the œdema attacks the cortex of the brain, coma and sopor ensue, if, however, it attacks the central parts, then eclampsia is the result. Recent authors recommend deep narcosis in eclampsia, Professor Späth, however, is accustomed to treat his cases, often with favourable results, by subcutaneous injection of morphia.

Railway Slaughters.

THE *Union Médicale* quotes the following interesting figures from a recent official return:—

Period 1 (1839 to 1854.)

	Passengers.
In France one person was killed by railway accidents out of	1,955,555
„ England „ „ „	5,256,290
„ Belgium „ „ „	8,861,804

Period 2 (1856 to 1839.)

In Belgium one person was killed by railway accidents out of	18,000,033
„ France „ „ „	13,323,014
„ England „ „ „	15,229,073

Period 3 (1872 to 1879.)

In England one person was killed by railway accidents out of	13,423,000
„ Belgium „ „ „	25,289,421
„ France „ „ „	27,879,000

THE epidemic of diphtheria in New York appears to have given way to one of scarlet fever, which latter caused 115 deaths in the week according to the last official return.

TYPHOID, diphtheria, and croup are still fatally prevalent in Paris; diphtheria in Berlin; small-pox in Vienna, and typhus in St. Petersburg.

Deceptive Thermometry.

SOME recent cases of high temperature prove the cunning of patients, in order to deceive their medical attendants. An incident happened in the clinique of Professor Valette, of Lyons, which will put physicians on their guard when the temperature is inordinately low. He was treating a young girl, æt. 11, for fever, by means of cold baths. She expressed a great abhorrence of cold water. One day, Valette, on visiting his patient, and examining the thermometric record, saw that a rapid deferescence had set in; yet the pulse was very frequent, and general condition alarming. No bath was given. Next day the same phenomena; temperature below 38° and 35° C. The professor found out the cause. The young woman's temperature was taken in rectum. Previous to introduction of thermometer, she introduced a piece of ice into rectum, so that the thermometric observations were at fault. The baths were given again. The young girl soon recovered.

THERE are now nearly 400 female physicians in practice in the United States. They are to be found in twenty-six of the States of the Union; but the majority of them are practising in New York, Massachusetts, and Pennsylvania.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Cardiff, Birkenhead, Huddersfield 16; Halifax 17; Leicester 19; Edinburgh, Wolverhampton 21; Leeds, Sunderland, Birmingham 22; Bristol, Nottingham, Portsmouth 23; Salford, Glasgow, Newcastle-on-Tyne, Oldham 24; Sheffield, Liverpool 25; London, Hull, Plymouth, Manchester 26; Bradford, Norwich 27; Derby, Blackburn 30; Preston 31; Dublin 33; Bolton 36; Brighton 40.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 29, Bombay 31, Madras 35; Paris 31; Geneva 36; Brussels 27; Amsterdam 27, Rotterdam 35, The Hague 23; Copenhagen 28; Stockholm 26; Christiania 23; St. Petersburg 51; Berlin 24, Hamburg 30, Dresden 25, Breslau 32, Munich 39; Vienna 37, Prague 34, Budapesth 44, Trieste 39; Turin 27, Venice 26; Alexandria 35; New York 34, Brooklyn 23, Philadelphia 26, and Baltimore 24. No returns have been received from Rome or Naples since December.

THE mortality from diseases of the zymotic class was somewhat in excess last week throughout the United Kingdom. Whooping-cough and measles were especially prevalent in Brighton. Scarlet fever was still high in Hull and Nottingham; whilst from measles the death-rate was 7.1 in Brighton, 5.4 in Blackburn, 4.7 in Norwich, and 3.9 in Bolton; and from fever 1.0 in Blackburn, and 0.9 in Oldham. The 37 deaths from diphtheria included 13 in London, 11 in Glasgow, and 3 in Portsmouth. Small-pox caused 9 more deaths in London and its suburban districts, one in Nottingham, one in Liverpool, one in Bradford, one in Leeds, and one in Hull.

Scotland.

(FROM OUR NORTHERN CORRESPONDENT.)

THE "FARMING" OF UNIVERSITY CHAIRS.—In our Retrospect of the Year (Dec. 28th, 1881), we spoke of the injustice which frequently obtains in the Edinburgh and Glasgow Schools, by the professor who has a large class under instruction, adopting the objectionable system of "farming" his chair. On Dr. Greenfield's appointment to the Chair of Pathology in the University of Edinburgh, we expressed our regret that he too should have "glided promptly into the principle of farming his chair to the best advantage to himself." A student writes us that "owing to the strictures in the *Medical Press and Circular*, Professor Greenfield has now a class on Saturdays for those who do not take his 'Practical.'" We congratulate Dr. Greenfield on this step in the right direction, which we trust may not be without its effect in other quarters. The system is a disgrace, and was invented by the late Professor Bennett. If the subjects taught in these "Practical classes" are necessary, the classes should be required for graduation or at once discontinued.

THE COMBE LECTURES.—Dr. Stirling delivered the seventh lecture to a crowded audience last week, in St. Catherine's Hall, Aberdeen. The subject was the physiology of the blood-vessels. The lecture was illustrated by many diagrams, by large views projected on a screen about twenty feet square by means of a lime light, and also by numerous experiments. The lecturer showed a beautiful experiment on the pulse with a long jet of gas, which vibrated with each beat of the pulse at the wrist, so that all the audience could see it. The action of the nervous system on the blood-vessels was illustrated by such conditions as blushing, and the pallor of rage or fear. At the close of the lecture a practical demonstration was given on a boy of what ought to be done in cases of injuries or wounds of blood-vessels to stop the bleeding before the arrival of the surgeon, or to enable the wounded person to be transported to a hospital.

BEQUESTS TO THE EDINBURGH ROYAL INFIRMARY.—During the past week the managers of this institution have received the sum of £13,500 (with £20 10s. 5d. of interest) from the estate of the late Dr. Thomas Hunter, Deputy Inspector-General of Hospitals. We understand that in accordance with the terms of Dr. Hunter's settlement the residue of his estate has been divided among several charities according to the pleasure of his executors, and that the sum above mentioned is the amount which they have seen fit to allocate to the Infirmary. The managers have also received intimation of a legacy of £500 bequeathed to the institution by the late Mr. James Hope, D.K.S., who was for upwards of forty years connected with it as a manager and law agent.

A METHOD OF STUDYING THE CIRCULATION IN THE FROG.—At a meeting of the Glasgow Philosophical Society, held on the 1st inst., in the Rooms, Bath Street, Dr. MacGregor Robertson Muirhead, Demonstrator of Physiology in the University, exhibited a method of studying the action of the frog's heart. The fluid used in the experiment was rabbit's blood, containing a slight solution of salt, and by means of a small mercurial manometer the action of the heart was rendered clearly visible. An addition of a small percentage of ether to the fluid was sufficient to stop that action, but upon the ordinary blood being again introduced, the beating of the heart recommenced.

EDINBURGH ROYAL MATERNITY AND SIMPSON MEMORIAL HOSPITAL.—The directors of this institution have just

received from the trustees of the late Dr. Thomas Hunter the sum of £2,100, being the share of Dr. Hunter's estate allocated to the hospital. The directors have, we understand, applied this amount towards the extinction of the debt of the hospital in connection with the building fund, which has thus been reduced to £200.

HEALTH OF EDINBURGH.—Last week the mortality was 91, and the death-rate per 1,000. Fully half the deaths were due to diseases of the chest. The three deaths from fever occurred in the old town, and were of the typhoid type. The southern suburbs were entirely free from zymotic mortality. Of the 130 births, 12 were illegitimate.

MORTALITY IN GLASGOW.—The deaths in Glasgow for the week ending with Saturday, the 25th ult., were at the rate of 25 per 1,000 per annum, against 28 in the preceding week, and 27, 24, and 32 in the corresponding periods of 1881, 1880, and 1879.

SIR ROBERT CHRISTISON'S APPOINTMENTS.—One by one the many lucrative posts held by the late eminent physician are being filled up. Last week Professor Greenfield was elected Medical Officer to the Standard Insurance Company, a post which was held by Sir Robert for nearly fifty years. Professor Grainger Stewart was also, we believe, a candidate for the office, the salary attached to which is about £400 per annum.

THE MONOPOLY OF HOSPITAL APPOINTMENTS.—At a recent meeting of the Directors of the Glasgow Royal Infirmary, Dr. Wm. Muir was elected an extra-surgeon, and Dr. Middleton an extra-physician. The latter appointment illustrates once more the power of University monopoly, Dr. Middleton, the nominee and assistant of Prof. Wm. T. Gairdner, being appointed over the heads of candidates of much more extensive experience, one of whom had for years previously discharged the duties of the office to the satisfaction of the then directors and students. The extent to which the monopolies of the Scotch Universities operate in repressing independent emulation and oppressing the rank and file of the profession is almost limitless. A man innocent of intellectual attainments, through the agency of social or political influence, obtains possession of an University chair; no matter what the quality of his teaching, students are compelled to take his course to qualify themselves for graduation. Error and nonsense are often perpetrated in this direction; but this is not all; he may become *ex officio* a director of an infirmary, and the baneful influence operates here. Professor Gairdner "lectures" on "The Practice of Physic" at the University of Glasgow; he is Physician to the Western Infirmary, and a Director of the Royal Infirmary. His influence extends, therefore, to the two infirmaries. Against Dr. Gairdner's influence it is almost impossible for any independent man in ordinary position to contend. Of all men he is worth conciliating, as his devotion to his satellites amounts absolutely to chivalry.

GLASGOW PROPOSED SOUTHERN HOSPITAL.—At a meeting of the Sub-Committee on Queen's Park (of the Glasgow Town Council), the Town Clerk reported that the Parks Committee, on the 26th July last, remitted to this Sub-Committee for consideration and report the memorial by the promoters of the proposed Southern Hospital, praying the Council to grant, on such terms as may be arranged, a site for the proposed buildings on a part of the lands belonging to them in the neighbourhood of the Queen's Park. This Sub-Committee has reported "that that portion of the recreation ground lying on the east side of the Langside Road, opposite the southern entrance to the Park, and near the old village of Langside, would be suitable for the purpose." This site is now under

the consideration of the promoters, who are expected to arrive at a decision in the course of the next few days.

Literature.

A MANUAL OF DENTAL SURGERY AND PATHOLOGY. (a)

We are not among those too prone to complain of the multiplicity of manuals and text books appearing now-a-days in every department of medical science, and therefore, we shall not altogether condemn Mr. Coleman for presenting the world with the work before us; although we are bound to say, that in the presence of several works on the same subject, which we could name, and which far exceed his, either in completeness or usefulness, the *raison d'être* of this manual is barely justifiable. We have, however, yet to meet with a work on any special subject of medicine or surgery, which can be pronounced perfect; and, until authors appear with not only the necessary scientific knowledge, but with the literary skill, needed in imparting their knowledge to the student, the learner must be content to laboriously glean from a collection of works on each subject, the information which he might reasonably hope to find in a single volume. The most we can say in praise of the work before us is, that it will form a useful addition to the dental library of the student and practitioner, but it is not a work which we can recommend as sufficient in itself for any one who desires to fully acquaint himself with the subject. In view of Mr. Coleman's high qualifications, and his deserved reputation as a teacher, the book is a great disappointment to us in more than one essential particular. In the first place Mr. Coleman's literary style is far from pleasant, and far from fluent. These faults may be forgiven in a purely scientific treatise, although their absence makes a great difference to the reader in the labour of mastering the subject. But besides this, the author is, in too many places, far from clear; and this is a blemish which cannot be lightly passed over. It is hardly possible to open a page of the book at random without coming across passages, the meaning of which, from faulty composition, is doubtful or obscure.

Here is a sentence to exemplify our meaning: "The condition termed necrosis, in which a tooth or bone has undergone changes other than a mere loss of vitality, which is not the case with simply dried teeth or bone removed from living or recently killed animals, where chemical change or decomposition has not ensued, is a barrier, and fortunately so, to the process of absorption, such tooth or sequestrum being got rid of by the general advance of bone to the surface; but where, through the resistance by obstacles, &c., necrosed temporary teeth or roots, are retained *in situ*, they form a common cause of irregularity in their permanent successors."

Of course, we know that nothing is more easy than to pick out here and there, even from the works of the best writers, sentences which show faults of style and composition; but the passages which we have quoted, and which is only a sample of what occurs almost in every page, is such as could not possibly escape from the pen of any sufficiently practised writer, and we submit that such writing furnishes evidence enough, from which safely to predict the inevitable comparative failure of the author in the task he has set himself.

From the preface it is difficult to make out quite what the author wishes to explain. He in one place says he thinks "it can hardly be said that any work perfectly suitable as a text-book has yet been produced." Implying that his work may provide what was wanted; but immediately afterwards he states that "he cannot venture to presume it will satisfy the requirements of the student as fully as the work of Mr. C. S. Tomes." One of the principal advantages of his book is, he thinks, the omission of a section on the anatomy and physiology of the teeth, which he says may not be needed by "many and especially the general medical student."

We cannot admit this. Without a knowledge of their anatomy and physiology it is impossible to understand the pathology of the teeth, or to rationally treat their diseases. It might

perhaps, be more convenient for the student to study these subjects in other works, but he cannot certainly dispense with a knowledge of them. We question whether the author has done wisely in omitting this subject. He devotes ten pages to the diseases of dentition, whilst he gives up not less than twenty-six pages to the subject of anaesthesia, a medical subject by no means essential to a treatise on dental surgery. No doubt there are practical points connected with this latter subject in its bearings on dental operations, which deserve mention in the work; but we consider that it would have been better to have omitted the great bulk of what the author has given, and to have presented in its place a sketch of the anatomy and physiology of the teeth, especially giving prominence to points bearing upon pathology and surgery. This prominence is probably given to the question of anaesthesia, for the reason that the author has had much more than common experience on the subject, and he has availed himself thoroughly of his opportunities; and similar reasons seem to have influenced the author consciously or unconsciously in dealing with other topics throughout the work. It is everywhere noticeable that he dwells always on such matters as have especially engaged his attention. This would not be objectionable, were it not that subjects equally important in a text-book are, in many cases slurred over or neglected.

Chapter 1. on the first dentition, containing a meagre description of the process of eruption of the teeth, is mainly taken up with an account of the diseases common at this epoch; a subject, the discussion of which, as we have already said, is not called for in a work of this kind. The author believes in the efficacy of bleeding the angle of the jaw, to relieve inflammation of the gums in teething; and he believes that the operation of scarifying the gums, in some cases, affords relief from the fact that he has been "occasionally asked by children old enough to do so, to perform it, from their recollection of the relief which they experienced on former occasions." The chapter following treats of irregularities and diseases of the temporary teeth, which are well and sufficiently dealt with. The chapter ends with an account of second dentition, in which the author gives his own views regarding the process by which the temporary teeth are shed. On what seems very insufficient evidence the fact that in very rare cases a temporary tooth remains *in situ* to the exclusion of its permanent successor, he draws the wide deduction that the shedding of the temporary teeth is in close relation with the advance of the permanent. We are at a loss to understand how such a generalisation can be put forth on such slight evidence, and especially in the presence of Mr. Charles Tomes's "demonstrations of the process of tooth shedding in the lower animals." The chapters on irregularities of the teeth, are, on the whole, well done. In describing the treatment of mal-placed teeth by mechanical apparatus, the author has omitted to point out the evil effects of violent pressure; and to caution the student that rapid movement of the teeth by such means, in many cases, leaves them permanently loosened and injured; that it is only by exercise of caution and patience that destructive inflammation may be avoided; and that, the more slowly the movement of the teeth is accomplished, the less danger is there of injury being inflicted.

A fair account of the divers theories as to the pathology of caries is given. The author's view is most in accord with the chemico-vital theory as expounded by Mr. C. Tomes; and he inclines to the belief that the process of caries has a pathological character. Having expressed this opinion he adds the following remarks which we cannot refrain from quoting as another sample of the kind of writing pervading the work. It is a passage of which we may, perhaps, guess the meaning, but which taken literally is incomprehensible, and certainly would be unintelligible to the ordinary student:—

"The teeth of every person must, in the mouth, like every other portion of the body—the hair, nails, and skin included—be continually expose, conditions which, but for a prevailing something, would ere long subject them to those changes which all highly complex nitrogenous bodies undergo when removed from its sphere or influence. It is this prevailing something, ceasing or changing with the loss of life in an individual, that immediately permits the existence of those affinities, or no longer opposes their action, which tend to break up into simpler form, the more complex chemical compounds of which an animal or vegetable body consists; and to which consequently we apply the vague term 'vital force,' which if actually a force, is probably, not more distinct from chemical than the latter is from electrical, or any of the so-called forces; indeed, it may be only one manifestation of

(a) "A Manual of Dental Surgery and Pathology." By Alfred Coleman, F.R.C.S. (Exam.), &c., &c. London: Churchill.

the chemical force. Whilst this exists, or remains unchanged, the teeth are, so to speak, protected from conditions, viz., moisture, warmth, action of acids, and bodies themselves undergoing changes, and decomposition, which would otherwise certainly allow the exercise which those affinities are ever exerting to break up complex organic compounds."

The limits of our space forbid an examination of the rest of the work; and we have said perhaps, enough to enable our readers to judge of the book's value. The chapters on the treatment of caries, and on extraction, are all of the same general quality; perhaps the best portion being that on the treatment of caries, and particularly on filling teeth. We have however felt it desirable to justify thoroughly the opinion we should have felt called upon to express, namely, that the book is, on the whole, a but slightly mitigated failure. We wished, moreover, to point out in what its defects mainly consist, in the hope that, after a thorough revision, a new edition may be produced which shall both fitly reflect the author's acquirements, and form a valuable contribution to dental literature.

BRISTOWE'S MEDICINE. (a)

DR. BRISTOWE'S "Theory and Practice of Medicine" is a classical work among students, few of whom have not, at some time or other, turned to its pages for information since it first issued from its author's hands. It is unanswerable testimony to the universal appreciation accorded to it that it has run into three editions in less than four years—a very unusual success for so considerable a book as the volume is. Dr. Bristowe's fame as a sound clinical teacher might very well be left dependant on his writings, and particularly on that portion of them embodied in the treatise under review. This is a perfect student's text-book, containing as much as needs be learned in order to make intelligent use of the opportunities presented of studying in the wards the diseases so faithfully described in its pages. It is also sufficiently succinct to serve as an accurate guide to the intending candidate for a medical qualification. Less bulky than other favourite text-books, it possibly contains to the full as much real instruction on the subject of disease; and in the matter of treatment it compares most favourably with all. The exigencies of the work demanded that compression should be closely studied, and on this account illustrative cases have been omitted in all sections of the volume. While admitting the high educational value of faithfully-recorded cases, and the incentive they afford to compare like cases that may be met with by the student, it is yet not impossible that in a text-book of medicine the narration of numerous clinical histories may do less good than is expected. As it is, Dr. Bristowe is careful to present a complete, and so far exhaustive, account of each particular disease; and it is the fault of the reader if he is unable, without the further assistance lent by cases in point, to recognise the actual malady itself. Dr. Bristowe has added to this English edition the invaluable article on Insanity, prepared by him for the second American edition of the work. Extensive alterations have, however, been introduced since it was first printed. Hemophilia and tetany are briefly noticed also, and numerous new illustrations are added. The short account of myxœdema needs correction. It is said by Dr. Bristowe never to occur in males; and the explanation of it given by him is scarcely as full as it might be. Taken as a whole, however, Dr. Bristowe's "Theory and Practice of Medicine" is a safe, efficient, and sufficient text-book, which may be adopted with full confidence, alike by candidates for examination distinctions, and by practitioners who desire to "brush up" their knowledge. It is the most excellent manual of medicine of moderate size in the English language, and is well worthy of the universal favour with which it is regarded.

THE MURDER OF DR. MACLEAN.—Sir Charles Dilke announced in the House of Commons on Monday, that H. M.'s Government were in correspondence with the Chilian Government, with the object of ensuring satisfaction to the relatives of Dr. MacLean, who was murdered by Chilian soldiers.

Correspondence.

VACCINO-TUBERCLE AND VACCINO-SYPHILIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The question raised by Dr. Cappie Shand in your issue of the 15th inst. merits serious attention. He has expressed a belief in the communicability of tubercle by the process of vaccination. It is no new doctrine, though it has never been a favourite one with the profession, but since our notions as to the nature and pathology of tubercle have been completely revolutionised by the experiments of Villemin, Klebs, and Burdon Sanderson, the question has been re-opened, is one of the first importance, and now awaits solution.

Tubercle, we know, is *not* a specific disease; is communicable by inoculation, and *can* be produced by artificial cultivation. We are told by Dr. Green that "the products of various inflammations (for the most part *inflammations of slight intensity*) may constitute the infective agents." Cohnheim, too, in his recent work declares "the test for tubercle" to be "the capacity of a morbid product when introduced into the body of a rabbit or guinea-pig to produce tuberculosis in the animals. What produces tuberculosis is tubercle; what fails to produce it is not tubercle." while Wilson Fox has shown that vaccine lymph so introduced *does* produce tuberculosis in the animal. If the premises be sound the conclusion of the syllogism is more obvious than pleasant. Tubercle has also been communicated to hens by vaccination. Then, again, the artificial cultivation of tubercle is on this wise. The product of a common non-specific inflammation in one animal is inoculated upon a series of animals, with the result of evolving a powerful poison swarming with bacteria, but which in its milder actions gives rise to tubercular disease. An analogy between this process and that of arm-to-arm vaccination has been suggested, and it is for those who extoll so highly the innocuity of humanised lymph to prove that such analogy does not hold.

It is a fact that infantile mortality, as a whole, is declining. It is also a fact that infantile mortality from scrofula and mesenteric disease are progressively increasing, and this coincidentally with the extension of vaccination. Is this coincidence a causal or a casual relation?

Dr. Shand suggests the substitution of animal lymph to avoid the alleged danger. He seems to forget that from 5 to 30 per cent. of bovines are tuberculous, and that this disease, according to Creighton, is communicable to man by the milk, while Mr. Fleming assures us that "the lymph is viruliferous."

Lastly, as a crucial test, M. Toussaint vaccinated a tuberculous cow with lymph absolutely pure. The vesicles progressed normally, and with the lymph obtained from them he vaccinated different animals, and everyone of these subsequently became tuberculous. I offer these facts as suggestive, rather than conclusive. The difficulty must be met; it is too vital to be put aside.

I am, Sir, yours, &c.,

W. J. COLLINS, M.B., B.S., B.Sc. Lond.

1 Albert Terrace, Regent's Park.

Feb. 26, 1882.

MIDDLE-CLASS HOSPITALS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following letter relating to the extension of the Home Hospitals movement is now being issued by the Managing Committee of the Association, and will doubtless be of interest to the readers of your journal.

When it was resolved, at a public meeting held at the Mansion House, in June, 1877, to take effective measures, by the aid of an Association on a proprietary basis, to provide an Hospital for Paying Patients, an appeal was made to the public for £10,000 capital to meet the first outlay. A liberal response was made, and a Home Hospital for such patients having since been successfully established at Fitzroy House, Fitzroy Squar, and, after a full year's experience, shown to be, not only necessary to meet a great want of the middle classes to be more than self-supporting, the first and principal object of the movement has been attained.

The freehold premises acquired in Fitzroy Square, however,

are found to be inadequate to the increasing demands for accommodation, and would, with the addition of the adjoining house, afford the larger space required, and enable the committee to reserve one house for each sex, and thus to add greatly to the comfort and well-being of both. Thanks to the treasurer, Mr. Frederick Cox, and to Mr. Henry C. Bardett, the hon. sec., the promise of a lease, with option to purchase the freehold of these adjoining premises at a fixed sum within a year's date has been secured. It only remains to find the required funds, estimated at £5,000, to ensure the full realisation of all the benefits originally contemplated, with a surplus income to form either a reserve for extending the movement, or a sinking fund for the gradual repayment of the capital advanced.

It has been suggested that this further sum might be raised by means of a limited company on a co-operative principle, and a transfer of the capital now existing on payment of an annual dividend. But any arrangement of this nature, though likely to provide the required funds, is so little in accordance with the feelings and intentions of the governors who liberally contributed the first capital sum, that it has been unanimously resolved to trust to the continued existence of this philanthropic feeling in the public mind and to make a renewed appeal for the smaller sum now required for the complete development of the original plan.

The committee feel that they may confidently appeal to the already numerous class of paying patients who have been inmates of the Home Hospital, and who have had ample experience of the advantages of the institution and the benefits it confers. They can bear testimony to its value, and cannot fail to feel a personal interest in promoting among their friends and connections contributions in aid of this extension and improvement of the accommodation at the Home Hospital.

I am, your obedient servant,

(Signed) NORTHUMBERLAND.

The Home Hospitals Association (for Paying Patients),
Fitzroy House, Fitzroy Square, London, W.

Obituary.

DR. HANS IRVINE, OF DUBLIN.

By the death of Dr. Hans Irvine, which occurred on Thursday last at the University Club, Dublin, the profession in Ireland loses one of its oldest and most respected members, who, though long retired from the practice of his profession, continued to enjoy the respect and affection of those who in time past had the advantage of association with him. Dr. Irvine was of a Fermanagh family of high social position, and his professional life gave evidence of the rank in which he was brought up by the fact that, in his relations with his professional brethren and the public, he was, in the strictest sense, a gentleman.

Dr. Irvine took the M.B. of the University of Dublin in 1833, and the Fellowship of the Irish College of Surgeons in 1837, and achieved such rank in the profession as to have served the Presidency of the College of which he was an *alumnus*, and for many years occupied a seat on its Executive Council. Having, in consequence of an infirmity of his hearing, retired from practice several years ago, he lived a good deal on the Continent, and only within the last two years resumed his place amongst his *confrères* in Dublin. Ripe of years, yet, so to speak, in the prime of his old age, he was carried off by an attack of bronchitis.

The concourse at the funeral gave evidence of the fact that his genial and estimable qualities had not passed from the remembrance of his medical brethren.

PASS LISTS.

University of Cambridge.—At a congregation holden on February 23rd the degree of Bachelor of Medicine was conferred on the following gentlemen:—

Cannon, Frank John, Trinity College.
Lane, James Oswald, St. John's College.

Royal College of Surgeons in Ireland.—The following gentleman has been elected a Fellow of this College:—

Frederick W. Higginson, Lic. Med. Dub., Civil Medical Officer,
Bengal Establishment, Government of India.

Army Medical Service.—The following is a list of candidates who were successful for appointments as Surgeons in Her Majesty's British Medical Service at the competitive examinations in London, on the 20th of February and following days:—

Westcott, S.	No. of Marks	2,295	McGill, H. S.	No. of Marks	2,045
Whitehead, H. R.	"	2,280	Pechell, A. A.	"	2,030
Skinner, B. M.	"	2,300	Tyrell, C. R.	"	2,050
Bartlett, C. R.	"	2,195	Hickman, J.	"	1,980
Rekitt, J. D. T.	"	2,175	Thomson, W. B.	"	1,975
Marsh, T. A. P.	"	2,150	Deane, H. E.	"	1,945
Kirkpatrick, R.	"	2,140	Stuart, S. O.	"	1,940
Alexander, A. C. A.	"	2,095			

Indian Medical Service.—The following is a list of successful candidates for appointments in Her Majesty's Indian Medical Service:—

Charles, H. H. R.	No. of Marks	2,495	Duncan, G.	No. of Marks	2,245
Barry, J. P.	"	2,452	Anderson, A. V.	"	2,030
Lyons, E. W. S.	"	2,385	Reilly, E. W.	"	1,945
	"	2,315	Scott, J.	"	1,900

There were but eight vacancies, but such is the popularity of this branch of the public service, that thirty-one candidates presented themselves at the competitive examinations, of whom the Military Secretary informs us twenty-seven were reported qualified.

NOTICES TO CORRESPONDENTS.

ALL CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinct signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

AN OLD CONTRIBUTOR.—The paper will have more weight with your name attached than under a *nom de plume*; we therefore propose inserting it thus in an early number.

DR. C. H. G.—Received, and will appear as soon as space permits.

A SANATORIUM FOR FEMALE INEBRIATES.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Permit me to draw attention to the claims of the Spalthorne Sanatorium for Female Inebriates, at Feltham, Middlesex. This institution, which, from standing in four acres of ground, is peculiarly adapted for its purposes, has done not a little good in reclaiming female drunkards. No intoxicating stimulants are administered to the patients. The management has sustained a severe loss by the death of Miss Antrobus, the late hon. sec.; and I regret to say that there are many vacancies for lack of funds. From personal inspection, I can cordially recommend this institution to the liberality of the benevolent. The Hon. Sec., Miss Rotch, 47 St. George's Road, Eccleston Square, S.W., will be happy to receive donations and subscriptions.

Yours, &c.

42 Grove Road, Regent's Park,
London, N.W.

NORMAN KERR, M.D.

A NEEDED ERRATUM.—In a recent number the *New Haven Register* inserted the following correction of a misprint:—"In the article upon Yale College, in our last, for 'alum water' read '*alma mater*.'"

MONSIEUR GUYOT (Paris).—Our present correspondent supplies us with all that transpires of importance in the medical world. We have not space for a weekly letter from a second correspondent in Paris.

MR. MEADOWS.—The statement was quite authentic; in fact, we received it officially.

DR. RECHIEDDI (Milan).—We cannot further add to our Exchange List.

MR. J. GILBERT SMITH.—Thanks; but it would be quite useless to us.

ESSAYIST.—The announcement of award is correct.

R. H. S.—We imagine Dr. G. to be rather the victim of a vicious system than an exponent of it, his present action would lead to the supposition that he desires gently to elbow it out. If this be so, he will have every encouragement and assistance from us.

MR. HENDERSON.—We have reconsidered the matter, and have decided that, for the reasons assigned in our letter, it would be undesirable to again refer to the subject.

IRISH GRADUATES' ASSOCIATION.—By an announcement in our advertisement columns, Irish graduates in London will have an opportunity of dining with their friends on Wednesday next at the Holborn Restaurant. This annual gathering is always looked forward to!

London as one of the most sociable and pleasant *réunions* of the season, and we doubt not many will be glad of this reminder.

MR. R. P. S.—The book was acknowledged in our issue for Feb. 22, and is now in hand for review.

MR. F. V. McDOWELL.—Your "Case of Fibrous Tumour in Sacrum" is marked for early insertion. Proofs will be sent you as requested.

GOVERNOR.—The appointments are the usual outcome of political jobbery. Since your letter was written the subject has been brought before the House of Commons and explanations of a very weak nature given; but no object would be now served by the insertion of correspondence thereon.

MR. N. P. M. (Edinburgh).—The lines form a capital *aide memoire*, but would be more suitable for our contemporary the *Students' Journal*.

COLONIAL APPOINTMENTS.—M. W. asks: (1) How are Colonial medical appointments obtained? (2) What amount of salary is given for such appointments?

[1. If our correspondent means Colonial appointments under Government, they are obtained through influence with the Secretary of State for the Colonies. 2. The salaries are from £400 a year upwards.—Ed.]

DR. S. (Castlemartyr).—The coroner is bound to pay for evidence whenever the witness pleases to demand the fee, and he has no right whatever to hold over the payment. Some coroners have been in the habit of doing so, but a Quarter Sessions process would speedily settle the matter.

ALBERT J.—We are informed by Messrs. J. & A. Churchill that Schroeder van der Kolk's work on "The Pathology and Therapeutics of Mental Diseases," translated by Rudall, can still be had; the price is 7s. 6d.

INSURANCE FEES.

To the Editor of the MEDICAL PRESS AND CIRCULAR,

SIR,—Will you kindly inform me on the following subject:—At the request of the secretary of an Assurance Company I examined a proposed life, and having filled the medical query sheet, sent it to his office, received my fee from him, and gave him a receipt for same, thus, I believed, concluding the transaction.

Subsequently he sent me a special sheet of medical questions in cases of corpulency, and requested me to fill and return it to him with as little delay as possible, which I did, at the same time intimating to him that my fee for so doing was a guinea, as I believed it to be a distinct responsibility from our former transaction. The secretary has repudiated my claim to a fee for the latter examination. Am I entitled to the second fee?

I am, Sir, yours faithfully,

J. T.

[Though we think the requisition for additional information a little unreasonable, nevertheless the report supplied would be regarded as part of the original transaction, and would not, in law, entitle you to a separate fee.—Ed.]

MIDWIFERY DIPLOMA.—The College of Surgeons of Ireland grants its midwifery diploma only to its own licentiates. The fee is £1 6s. if taken out within a month of the diploma in surgery; £2 2s. if after that date. The College of Physicians charges £1 1s. extra to the diploma fee if the midwifery diploma be taken out within a month, or £3 3s. if afterwards. The hospital attendance costs £10 10s. at the Rotundo, or 24 4s. at the Coombe.

GENERAL PRACTITIONER.—It is not uncommon for the specific gravity of urine to reach 1080, or even 1085, 1040, without containing sugar. When such is the case, the urine is usually found to contain urea in great excess, and this may be recognised by adding nitric acid, when, after standing for a time, crystals will be deposited in great quantity.

EXPERT.—There is an excellent report of fifty cases of Tendon Reflex in the later stages of Hemiplegia published in the last issue of the St. Bartholomew's Hospital Reports by Dr. Ormerod. The cases are arranged under four tables.—1. Ten cases of tendon reflex equal in corresponding limbs of sound and paralysed side (doubtful excess on paralysed side). 2. Two cases greater in the sound than in the paralysed side. 3. Thirty-two cases—no excess on sound side, but excess in leg or arm of paralysed side. 4. Five cases—tendon reflex greatest on paralysed side, but exaggerated also on sound side. Dr. Ormerod concludes that exaggerated tendon reflex is a delicate indication of that condition which, in an advanced stage, causes rigidity.

THE SOCIETIES, COLLEGE LECTURES, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—This day (Wednesday), at 4 p.m., Prof. W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Edentata."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—This day, at 5 p.m., Gulstonian Lectures: Mr. W. Ewart, "On Pulmonary Cavities—their Origin, Growth, and Repair."

LAMETARY INSTITUTE OF GREAT BRITAIN.—This evening, at 7.45 o'clock, a Paper on the "Range of Hereditary Tendencies in Health and Disease," by Mr. George Gaskoin.

HURTERIAN SOCIETY.—This evening, at 7.30 o'clock, Council Meeting.—8 o'clock, Dr. Bedford Fenwick, "On Venesection in Cardiac Disease."

ROYAL MICROSCOPICAL SOCIETY.—This evening, at 8 o'clock, General Meeting.

EDINBURGH OBSTETRICAL SOCIETY.—This evening, at 8 o'clock, Papers: "Clinical and Experimental Observations on the Bladder during Parturition," by Dr. J. Halliday Croom.—"On Some Points in the Physics of the Rectum and Bladder," by Dr. D. Barry Hart.—"Note on a Unique Cause of Delay in the Third Stage of Labour," by Dr. D. Barry Hart.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Thursday, March 9th, at 8½ p.m., Dr. Walter Edmunds, "On a Case of Suppurative Ophthalmitis after Ligature of Common Carotid."—Mr. Lawford,

"On an Unusual Case of Gunshot Injury of the Eye."—Mr. Warren Tay: (1) On a Case of Optic Neuritis after Concussion of the Brain." (2) "On a Case showing Condition three years after Optic Neuritis from Injury to the Head."—Dr. Sidney Coupland, "On a Case of Optic Neuritis following Contusion of the Brain."—Mr. McHardy, "On a Case of Extensive Retinitis following Injury to the Head."—Mr. Fitzgerald (Dublin), "On a Case of Defective Vision in a Seaman."—Dr. Bralley—microscopical specimens: (1) From a Case of Retinal Detachment simulating Sarcoma of Choroid; (2) (For Mr. Mason, of Bath) From a Case of Sclero-corneal Tumour.—Mr. Snell (Sheffield), "On a Case of Sympathetic Ophthalmitis setting in after Excision."—8 p.m. Mr. Nettleship, "On a Case of Atrophy of Optic Disc after Orbital Erysipelas" (living specimen).

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Friday, March 10th, at 4 p.m., Prof. W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Edentata."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Friday, March 10th, at 4 p.m., Gulstonian Lectures: Mr. W. Ewart, "On Pulmonary Cavities—their Origin, Growth, and Repair."

ROYAL INSTITUTION.—Friday, March 10th, at 8 p.m., Mr. J. W. Swan, "On Electric Lighting."

CLINICAL SOCIETY OF LONDON.—Friday, March 10th, Mr. G. Lawson, "On a Case of Chimney Sweep's Cancer of the Axilla treated by Excision of the Growth, Ligature of Axillary Artery, and Amputation at Shoulder-joint."—Mr. H. Marsh, "On a Case of Aneurism of Axillary Artery, Ligature of Subclavian, Rupture of the Sac, Amputation at Shoulder-joint; recovery" (patient to be shown).—Dr. Mahomed, "On a Case of Myxodema improving under treatment" (patient to be shown).—Mr. Warrington Haward, "On a Case of Removal of the Hypertrophied Spleen."—The following living specimens will be exhibited:—A Case of Radical Cure of Congenital Hernia in the Adult, by Mr. C. H. Golding Bird; a Case of Cured Spina Bifida, by Mr. Pease Gould; Two Cases of Universal Ichthyosis in Adult Females, by Dr. B. O. Connor.

ROYAL INSTITUTION.—Tuesday, March 14th, at 8 p.m., Prof. John G. McKendrick, "On the Mechanism of the Senses."

Vacancies.

Epsom Union, Surrey.—Medical Officer. Salary £50, with the usual extra fees. Application to the Clerk of the Guardians by March 21st.

Kent County Lunatic Asylum, Chartham.—Second Assistant Medical Officer. Salary £120, with Board. Applications to the Clerk of the Committee before March 21st.

Mountmellick Union, Maryboro' Dispensary.—Medical Officer. Salary £100, and £20 as Medical Officer of Health. Election March 17th.

North Wales County Lunatic Asylum, Denbigh.—Medical Superintendent. Salary £450, with certain allowances. A knowledge of Welsh desirable. Applications to the Chairman of Committee by March 29th.

Royal Hospital for Diseases of the Chest, City Road London.—House Physician. Salary, £20 per annum. Applications to the Secretary by March 9th.

Appointments.

BAIN, W., L.R.C.P.Ed., L.R.C.S.Ed., Resident Medical Officer to St. Mary's Hospital and Dispensary for Diseases of Women and Children, Manchester.

GOLDING, J. F., M.D., Physician to the North Infirmary, Cork.

HOPPER, H., L.R.C.P.Ed., L.R.C.S.Ed., Medical Officer to the Herworth District of the Gateshead Union.

KAY, J., L.R.C.P.Ed., L.R.C.S.Ed., Junior House Surgeon to the Stockport Infirmary.

LAURENT, E. A. O., M.B.Lond., M.R.C.S., Resident Surgeon to the Bedford General Infirmary and Fever Hospital.

MEAD, G. B. O., L.R.C.P.Lond., M.R.C.S., Medical Officer of Health to the Newmarket Urban Sanitary District.

ROBINSON, J. J., M.B. T.O.D., House Surgeon to St. Mark's Ophthalmic Hospital, Dublin.

WHITLA, Dr. W., Physician to the Ulster Children's Hospital, has been appointed Physician to the Belfast Royal Hospital.

WOOLBY, J. B., L.R.C.P.Lond., Physicians' Assistant at the Bristol General Hospital.

Births.

KEMP.—March 5, at 101 Jermyn Street, London, the wife of J. E. Kemp, L.R.C.P., M.R.C.S., of a son.

HAYES.—March 1, at 18 Merrion Square, Dublin, the wife of P. J. Hayes, F.R.C.S.E., of a son.

LUBBOCK.—March 5, at 19 Grosvenor Street, London, the wife of Montagu Lubbock, M.D., of a son.

OULTON.—March 1, at the Meath Hospital, the wife of Henry W. Oulton, M.D., Resident Surgeon, of a daughter.

THOMSON.—Feb. 27, at 40 Ladbrooke Grove, Kensington Park Gardens, London, W., the wife of Dr. Symes Thomson, of twin daughters.

Deaths.

CROFT.—Feb. 26, Robert Charles Croft, L.R.C.P.Ed., M.R.C.S., of Camden Road, aged 55.

DENNE.—March 3, at Eastbourne, William Denne, F.R.C.S., Medical Superintendent to the Cos. Asylum, Arlesey, Beds, aged 78.

IRVINE.—March 2, at the University Club, St. Stephen's Green, Hans Irvine, M.D., of Rutland Square, Dublin, deeply regretted.

GUY.—March 3, at Dover, William, the youngest son of Thomas Guy, M.D., F.R.C.P., Inspector-General of Hospitals, aged 29.

STURROCK.—March 4, at Broughtly Ferry, Dundee, David R. Sturrock, M.D.

SUTHERLAND.—Feb. 21, at Moray House, Lee, Kent, John Sutherland, M.D., Inspector-General of Hospitals, Bengal.

SCHERING'S CHINOLINE TARTRATE,

According to Dr. DONATH,
And all other Salts of Chinoline.

Chinoline Salts are destined to an important part in Medicine.

SCHERING'S CHINOLINE TARTRATE is almost entirely free from smell, and has none of the objectionable properties which other similar products have shown.

To be obtained of all Wholesale and Retail Drug and Chemical Houses.

Sole Wholesale Agents: **A. & M. ZIMMERMANN, 21 Mincing Lane, London, E.C.**

**STRUTTS'
ABSORBENT
COTTON WOOL**

is "indispensable as a dressing in surgical cases" (EDWARD GAYLOR, L.R.C.P., &c., &c.). "Can confidently recommend it to others" (J. W. SMITH, L.R.C.P. Lond., M.R.C.S.E.). "The best medium for surface application of antiseptic and other fluids" (H. LOMAS, L.S.A.L., Belper). "I consider it of the greatest value in surgery. Its immense power of absorption affording a ready means of cleaning wounds, and applying fluid dressings" (C. B. DUNN, M.R.C.S.).

To be had of **W. G. & J. STRUTT, Belper, Derbyshire, and 45 Fore Street, London, E.C.,** or through the Wholesale Houses.

QUINQUININE (MACKEY'S) Registered.

Takes the place of Quinine at considerably less price. Every genuine bottle has the name Mackey, Mackey, & Co.

"Therapeutically Mackey's Quinquinine equals Sulphate of Quinine.—THOS. HORNE, L.R.C.P., Sandwich. Price, in 1 oz. vials, 5s

MISTURA CERII COMP. (MACKEY'S). By Royal Letters Patent.

Specific for Obstinate Vomiting of any Kind.

A SPECIFIC FOR VOMITING IN PREGNANCY, Sick Stomach, in alleviating the pain and vomiting in Carcinoma and general Chronic Vomiting and reliable remedy for the cure of indigestion, &c. Dose 15 to 60 minims IN BOTTLES 5s. and 9s.
"The MISTURA CERII Co. is particularly successful in all cases of irritable stomach, dyspepsia, &c., and I HAVE FOUND IT ALLAY VOMITING (no matter the cause) WHEN ALL OTHER REMEDIES HAVE FAILED.—R. T. W. SMITH, F.R.C.S., &c.

MACKEY'S MIST. BISMUTHI COMP. Dr. Browning's. Registered. Tonic Digestive

Dose 15 to 20 minims. The only reliable preparation of Bismuth. The *Lancet* says:—"Bismuth could hardly be given in a better form."
"I have used the Mistura Bismuthi Comp. prepared by Messrs. Mackey, Mackey, & Co., and have found it most EFFICACIOUS AND FAR SUPERIOR TO ANY OTHER PREPARATION OF BISMUTH THAT HAS COME UNDER MY NOTICE.—C. EATON BAKER, M.R.C.S., &c.

CAUTION.—The large demand for our specialities has caused systematic imitations. The Profession is earnestly requested, if not ordering direct, to give special prominence to the word **MACKEY'S** e.g. Mackey's Quinquinine; Mackey's Mist. Bismuthi Co.; Mackey's Chlorodyne, all soluble Compounds of Cerium, and improved preparations of the Hypophosphites.

MACKEY, MACKEY & CO. (*Wholesale and Export Druggists and Manufacturing Chemists*), 1 & 2 BOUVERIE ST., LONDON, E.C.

IMPROVED CLINICAL THERMOMETERS'

YEATES & SONS' Improved Clinical Thermometers, with fixed Zero, extremely Legible and Indestructible Index, the best Clinical Thermometer in the market, 10/-

Patent Clinical Thermometer, with Magnifying Stem, 10/-

All these Thermometers are compared with Kew standard, and are guaranteed correct.

Ordinary Clinical Thermometers, in Boxwood of Metal Cases, 7/6.

YEATES & SONS' Constant Current Battery, with Conductor and one Directing Plate.

Ophthalmoscopes of every Approved Construction, from 15/- upwards.

YEATES & SONS,

2 GRAFTON STREET, DUBLIN.

SIR JAMES MURRAY'S ORIGINAL FLUID MAGNESIA.

THE PUREST, BEST, AND CHEAPEST PREPARATION,

HAS been prescribed for Sixty Years as the best Remedy for Acidity, Indigestion, Heartburn, Gravel, and Gout; and mixed with his Lemon Syrup, forms a pleasant effervescing Aperient especially for Ladies and Children.

Sold by all Chemists, in Bottles, double the usual size, at 1s. 2s. 6d., and 3s. 6d. each; and in Gallon and ½-Gallon Jars for Dispensing.

HIS CORDIAL FLUID CAMPHOR
Is also extensively prescribed for weak nerves, low fevers, cholera and diarrhoea. Bottles, 1s. and 2s. each.

KANOLDT'S

APERIENT TAMARIND LOZENGES.

From the pulp of the Tamarind fruit, without irritating or griping substances. A mild and effective laxative of very appetizing appearance, agreeable to take, and good in all climates. See that no inferior similar preparations are substituted.

The genuine article bears on every box the name of the

Sole Agent for Great Britain—

PAUL METZ, 10 JEWIN STREET, LONDON, E.C

Recommended by all leading Physicians. Particulars post free. In elegant boxes at 1s. 6d., and 2s. 6d. each.

CLINICAL LECTURES ON SYMPTOMS.

Delivered in the Wards of the Hospital.

By FREDERICK T. ROBERTS, M.D., B.Sc., F.R.C.P., Professor of Materia Medica and Therapeutics at University College; Physician and Professor of Clinical Medicine at University College Hospital; Physician to the Brompton Consumption Hospital, &c.

LECTURE IX.—SYMPTOMS CONNECTED WITH THE HEART.—(Continued).

3. ANOTHER group may be made to include *general objective symptoms*, or those which are *remote*, but not connected with particular organs. These are often at once evident on the most casual examination, and may be conspicuous in the appearance of the patient. In this connection *posture* may first be referred to, which in not a few instances of cardiac disease is highly significant. Thus, the patient may not be able to lie on the left side, on account of the disturbance of the heart thus induced; while inability to remain in the recumbent posture is in some cases a striking feature, on account of the cardiac disorder, dyspnoea, and the accompanying sensations thus induced; the patient requiring, therefore, to sit or to be propped up in bed, or even being only comfortable when resting in a heart-chair. We have had some marked cases in the wards during the present session illustrating this point, and showing the great benefit to be derived in treatment from the use of this chair. Under certain circumstances, however, the recumbent posture can alone be adopted, there being a tendency to syncope if the patient is raised. In the next place, the effects of *movement* or *exertion* on the part of the patient must be noticed. Such an act in cases of certain heart-affections sets up at once prominent disturbance, indicated by hurried breathing, excited or disordered cardiac action, a tendency to syncope, or other phenomena which may be obvious in the aspect of the patient. Indeed, in some forms of these affections, it is very instructive to test the effects of a little exertion with reference to the symptoms just indicated.

The more evident phenomena which come under this group are of considerable importance, and when present, always deserve careful attention. They are of the following nature:—

a. Excessive action of the heart may be revealed in the face and neck by *flushing* and *pulsation of vessels*, whether it be functional or due to organic disease. A peculiar symptom is noticed in some cases of aortic regurgitation with enlarged heart, which is very characteristic, namely, that when a part of the skin of the forehead is irritated so as to make it red, the redness is increased with each ventricular contraction and diminishes during the diastole, the spot, in cases of marked regurgitation, becoming absolutely pale, so that there is a striking alternation of flushing and pallor over it.

b. The head, face, and neck, not uncommonly present signs of *venous congestion* in cases of cardiac disease. This may be indicated by a more or less bluish or purple colour, especially of the lips, nose, and ears; enlargement or tumefaction of the features, or puffiness with a bloated appearance; watering of the eyes; and permanent distension of the capillaries and small veins, so that they become visible in large numbers, forming networks. The hands may also exhibit a more or less congested appearance, and likewise the feet; and the fingers and toes may in time assume a "clubbed" condition. It is not uncommon for the legs to present a congested appearance for some distance up. These phenomena are liable to become aggravated under certain circumstances, as from exposure to cold, or any temporary pulmonary complaint which tends further to impede the circulation, and to impair the aeration of the blood. In a marked or extreme form they are seen in the condition termed *cyanosis*, which I have already mentioned more than once, and which may now be more definitely explained. Cyanosis signifies the peculiar colour which is observed in certain cases, where the venous circulation is gravely interfered with, and at the same time the blood is usually very imperfectly aerated; in some instances there is also an intimate admixture of arterial or venous blood; or still more rarely the entire blood is venous in character. Cyanosis, as a persistent condition, is usually associated

with some cardiac affection, especially certain forms of congenital disease, but this is not always the case. As I have stated in a former lecture, I have met with a case where it was extremely marked in the face and neck, the arms, and the upper part of the body, in connection with local obstruction of the superior vena cava. Cyanosis is also the appearance which attends acute or chronic suffocation; and it may be decidedly present in cases of severe bronchitis complicating extensive emphysema. It will be convenient to describe it here once for all. The phenomena already mentioned are present in an aggravated form, and the longer the cyanotic state lasts the more marked do they become. The colour of the skin is not necessarily blue, as the word literally signifies, but it may be purple, clarety, or leaden. It varies much in degree, being most obvious in the lips, nose, and ears, and in the fingers and toes, and it may be practically confined to the face and the hands and feet. Moreover, it is not uniform, the surface being often mottled. The colour is liable to be intensified by anything which temporarily further impedes the venous circulation, or diminishes the aeration of the blood, such as disturbed cardiac action, the act of crying or coughing, exposure to cold, or an attack of bronchitis.

c. Not only may the patient feel cold, but there is also actual objective coldness in some forms of cardiac disease, which may be evident to the touch, or determined by the clinical thermometer. This is usually, but not necessarily, associated with more or less of the phenomena just considered; and, in its most marked form, accompanies confirmed cyanosis. The coldness is especially noticed in the hands and feet, and in the prominent features, where the cyanotic appearance is most obvious.

d. *Anæmia* is a striking objective appearance in certain cases of heart disease, and this organ should be always remembered as one of the causes of the anæmic condition. At the same time particular caution is requisite not to mistake the symptoms and physical signs often associated with the heart in cases of marked anæmia, for evidences of actual disease. Cardiac disease may, however, give rise to very obvious pallor of the face, with a more or less bloodless aspect of the visible mucous membranes. Sometimes there is a combination of cyanosis and anæmia in the same case. The condition is often partly due to an actually impoverished state of the blood, the red corpuscles being deficient; partly to a deficient supply to the arterial system. Temporary pallor is, of course, a symptom of faintness or fainting. Persistent anæmia is especially noticed in cases of marked aortic disease, particularly regurgitation.

e. *Dropsy* constitutes one of the most important symptoms belonging to the group now under consideration, which has to be noticed in relation to cardiac diseases, and we have had ample opportunities during this session of recognising their relationship, while we have at the present time illustrative cases under our observation, to which I have often drawn your attention. You will readily understand that this dropsy is the direct and natural result of the venous congestion which diseases of the heart so often induce; but it may be aided by the state of the blood itself, or by disease of the vessels or of the kidneys, which may accompany the cardiac mischief. Therefore, without entering into details, having already discussed with you fully the subject of dropsy, let me remind you that in this instance it follows the laws of gravitation, and begins where the venous congestion is most marked, namely, in both feet and ankles, from which it spreads upwards, reaching the knees, the thighs, the scrotum, or even the trunk in some instances, while effusion may also take place into serous cavities. Thus the dropsy becomes more or less "general." When the patient remains in the recumbent posture, the dependent parts of the body may be alone œdematous, or more so than the anterior part. The progress of the dropsy is very variable as regards its rapidity, being in most instances chronic, sometimes tolerably rapid. When not considerable, you will have noticed that we can modify it very much by posture; and by keeping the legs raised we have been able sometimes even to get rid of it entirely, without having recourse to any

further treatment. Moreover, by the aid of certain therapeutic measures we have succeeded in getting rid of the time of very extensive dropsy in some of our cases, and have discharged the patients; but unfortunately the improvement has only been temporary, and they have all returned again, the cardiac condition which caused the dropsy being permanent and incurable. Some of the cases in which we have obtained marked success in treatment, have been those in which the dropsical condition was temporarily aggravated by a pulmonary complication, still further embarrassing the circulation, which we have been able to remove. The skin of the legs has in some cases presented the appearance and colour of venous congestion, but by no means in all; in one instance also there was a cyanotic aspect of the face in a moderate degree. You have to be on your guard when there is much dropsy of the legs or scrotum, lest untoward complications should supervene, such as erythema, erysipelas, or gangrene. Unfortunately in one case this session the lesion last mentioned did actually occur.

f. *Pyrexia* must be mentioned as a general condition which may be associated with cardiac affections, especially those which are acute. Probably it may also arise in connection with the lodgment of emboli in organs, which come from the heart. Under certain circumstances the fever runs high and assumes a typhoid character, and indeed the symptoms become those of septicæmia, owing to the admixture with the blood of septic matters from the inner surface of the heart, as in ulcerative endocarditis, of which we have had one instance this session in the wards.

(To be continued).

THE CAUSES, SYMPTOMS, AND TREATMENT OF TETANUS.

A Clinical Lecture delivered in the Meath Hospital and its Dublin Infirmary.

By LAMBERT H. ORMSBY, F.R.C.S.,
Lecturer on Clinical and Operative Surgery.

(Concluded from page 182.)

Pathology and Morbid Anatomy.—It is notorious that post-mortem examinations on patients who have died of tetanus up to a very late period gave very negative results, and, as a matter of fact, very little change, if any, was found in the terminal ends of the nerves supposed to be irritated; or yet in the spinal cord, which is certainly the deranged nerve centre believed to produce the disease.

In 1864 Dr. Lockhart Clarke (a) made a very careful examination of the spinal cords of six persons who died of tetanus, and in each case his results corresponded very closely to each other, viz., an abnormal enlarged condition of the blood-vessels throughout the grey matter, especially in the posterior horns, and granular disintegration of the nerve tissue, were uniformly present.

Dr. Lockhart Clarke believes, as the result of his researches, that tetanus depends *first* upon an excessively excitable state of the grey nerve tissue of the cord induced by the hyperæmia and morbid condition of the blood-vessels, and the exudation and disintegration resulting therefrom; and *second*, that the spasms are the result of the persistent irritation of the peripheral nerves, by which the exalted excitability of the cord is aroused; and thus the cause which at first induced in the cord its morbid susceptibility to reflex action, is subsequently the source of that irritation by which the reflex action is excited.

Dr. Dickinson (b) found enlargement of the blood-

(b) "Description of the Spinal Cord in a Case of Tetanus": *Medico-Chirurgical Transactions*, vol. i., 1865, p. 267.

vessels throughout the grey substance of the cord, with perivascular exudation, rupture of the blood-vessels in many places, and granular disintegration.

Dr. Clifford Allbutt (a) has reported the results of examinations on the spinal cords of four cases that died of tetanus, and confirms the observations of other pathologists concerning this disease. He found diminution of the consistence of the cord of various degrees and situation; hæmorrhage in two cases visible to the naked eye; enlargement of the blood-vessels; exudation of a granular plasma surrounding the vessels; enlargement of the cells of the grey matter and the granular degeneration of Clarke. Outside the spinal cord he found the nerve congested and thickened, and bathed in inflammatory products. These conditions were also found by Drs. Clarke and Dickinson.

Dr. Fox (b) examined the cords in four cases. In one the only abnormality remarked was dilatation and distension of the spinal pia mater. In the others he found softening, hæmorrhage, amyloid bodies in the grey substance, and thickening of the vessels.

Michaud (c) also examined the cord in four cases of tetanus. He found as a result of his examination that the grey matter presented a general red appearance. The vessels were enormously enlarged. There were numerous free nuclei and foci of perivascular exudation. The gray substance, and especially the posterior commissure, was the seat of these alterations, which, according to him, consist essentially in a proliferation of the nuclear elements of the connective tissue. This pathologist considers tetanus to be an acute inflammation of the grey tissue of the cord.

It has also been frequently observed that when either of the upper extremities is the seat of the wound or injury that induces the disease, the lesions of the cord are found in the cervical enlargement about the organ of the brachial plexus, and when either the lower limbs are injured, the spinal lesions are found in the lumbar enlargement.

The nerves carrying the impression from the wounded part have been found red and inflamed by Airlong, Tripier, and Michaud. But this inflamed condition is by no means constant, frequently the nerves at the injured part have been found in no way changed from their normal condition.

Bilroth states that his examinations of the spine and nerves in cases of tetanus have thus far given only negative results. This testimony seems to bear out the experience of many other pathologists. However, it may be inferred in these cases that the centric spinal lesions are progressive, and in each case the patient succumbed before there was time for any perceptible change to take place in the grey matter of the cord, and therefore, as a consequence, the organic derangements, whatever they may be, do not occur. In those cases that recover it is most probable that the centric lesion never goes further than hyperæmia, and stops there before there is time for any other derangement to take place.

In pursuing the pathology of this disease farther, very little more may be expected. We have ascertained this much, however, that the pathology of the disease is still obscure, and by no means fully proved. Further investigation must be made before we can definitely say what is the exact condition or origin that produces the disease.

Hammond says:—"From the consideration of all points bearing on the subject we are warranted in concluding that tetanus essentially consists in a morbid

exaltation of the function of the spinal cord as a nerve centre. We are led, therefore, by observation and experiment to the conclusion that the lesion of tetanus is seated in the grey matter of the spinal cord, and that although we cannot at present affirm an absolute identity of the lesions in each case, we have enough data to enable us to say in general terms that tetanus is essentially an inflammatory affection of the grey matter of the spinal cord." (a)

In pursuing the pathology of this important disease any further, very little more information of a useful nature can be advanced. We have ascertained this much, however, that the spinal cord is the deranged centre in tetanus producing this very peculiar train of spasmodic muscular seizures, the why and the wherefore of which, I believe, is still veiled in obscurity; and as regards the exact condition or primary origin of tetanus, the matter is still considered by pathologists to be a *questio vexata*, and one well worthy of further investigation.

It having been previously observed that acute traumatic tetanus is so uniformly fatal, it is of the greatest importance to attend to whatever may assist in detecting the disease at the very onset, or in warding it off altogether, as it is sometimes far easier to prevent a disease than to cure it, and this most especially applies to tetanus. Richeraud states that in wounds threatening convulsion and tetanus, a persevering extension of the limbs during sleep often is present long before any affection of the lower jaw or other symptoms appear; and particular attention should be paid to any premonitory symptoms of this kind after punctured or extensive lacerated wounds, especially of tendinous or ligamentous parts, particularly in injuries of the feet, hands, knee-joint, back, or where nerves are believed to be torn, stretched, or lacerated. Still more attention should be paid if they are accompanied with increase of pain at the injured part, irritation, restlessness, nervous twitches, pain and difficulty of opening the mouth and swallowing; and I still would give you further advice on this subject. Whenever you see a suspicious-looking injury, known to occasionally be the starting point of tetanus, whether you have premonitory symptoms or not, at once commence a preventive or anticipatory line of treatment. You will ask me what does this consist in. 1st. Place your patient in a favourable hygienic condition. 2nd. Attend to the state of the wound or injury by applying the appropriate line of local treatment, so as to remove the irritating cause, and then to have the parts cleansed in the most perfect manner. 3rd. The bowels to be kept open and moderately free all the time until danger is over; Peiles' anti-tetanic pill ought to be administered frequently. 4th. A mixture containing bromide of potassium should be given at once to anticipate and allay nervous irritation. 5th. The patient should be kept under observation, and seen every day—and oftener if necessary—until after the first fortnight following the injury.

Treatment.—We now come to the important question of treatment, a subject that is surrounded with a great deal of difficulty and perplexity, for, as is well known, the disease baffles every mode of practice; and in some cases they get well under the employment of the very same remedies that proved so useless in similar cases of the disease. One plan has occasionally succeeded, and the same plan in other hands has just as often been perfectly useless. The great difficulty, therefore, is to ascertain amongst numerous lauded accounts what is, on the whole, the plan most likely to be followed by the least ill-success, for you find in medical journals, and other scientific periodicals, that a case of tetanus was cured by adopting a certain remedy or other line of treatment. One case, I may observe, is not sufficient to prove the undoubted efficacy of this or that line of

treatment. I do believe that, like some other diseases, there are in tetanus cases that will recover, and there are cases that will not recover, no matter what is done; and we might, therefore, divide such cases into *ill-doing* and *well-doing*. Another point about this question that ought not to be lost sight of, and that is, suppose a number of remedies are administered, individually or collectively, in a given case of acute traumatic tetanus, coupled with various forms of local treatment, and that case fortunately recovers, is it rational reasoning to suppose that one remedy alone out of the number used, or one line of treatment alone, should get the whole credit of curing the case? I do not think it at all likely that if constitutional treatment was altogether omitted, there would be the slightest hope for the patient's ultimate recovery if we were to depend on local treatment alone.

It may be again observed that the indication of cure which is generally applicable to nearly every other disease, namely, the immediate removal of the exciting causes, does not, as a matter of fact, give one much assistance in an affection which is the consequence of causes which in general have ceased to act, or which is not in our power to remove or control. It is certainly rational to suppose, where we have local irritation present produced by a compressed, stretched, or torn nerve, the most effectual method of counteracting its effects on the system would obviously be to immediately intercept all communication between the seat of local irritation and the grey matter in the spinal cord.

If, on the other hand, however, the disease has already established itself, and the severe train of symptoms fully developed, it does not appear that this would succeed in arresting the course of the disease, particularly when changes and degeneration have taken place in the spinal cord. It seems analogous to the old saying of "Shutting the stable door when the steed has flown." Experience also fully proves that amputation of the limb, from the injury of which the tetanus has followed, will seldom procure even a mitigation of the symptoms, if performed at any period after the symptoms of tetanus has set in.

Baron Larrey was the great advocate of early amputation where tetanus depends upon a wound of the extremities; and furthermore, wishes this recommendation to be carried out chiefly in chronic cases, and only on the very first accession of the symptoms.

The treatment of tetanus may, therefore, be divided into local and constitutional, and first we will consider the steps that ought to be taken with reference to the injured part itself.

Local Treatment.—The part should be carefully cleansed from all impure or foreign matter; the wound ought to be poulticed with linseed meal well saturated with laudanum, and the dressing changed three times a day. Mr. Liston recommends the surgeon to cut down on the part above the injury by a Δ -shaped incision, cutting it off or isolating the injured part, so as to intercept the nervous current to the cord.

Professor Fayer, of Calcutta, relates a case of tetanus caused by a wound in the hand, and relieved by section of the median nerve above the injury.

Amputation before mentioned was strongly recommended by Larrey in certain cases. It is recorded that Mr. Rey, in 1845, amputated a leg on account of tetanus which had appeared six days after an unreduced dislocation of the astragalus. The symptoms disappeared at once after the operation. On dissecting the foot the posterior tibial nerve was found to have been put violently on the stretch by the projecting astragalus.

Nerve Stretching.—This line of local treatment has been adopted, by way of experiment, in certain cases by Professor Esmarch, of Kiel, and Professor Nasbour, but the results of these surgeons by this mode of treatment have been most discouraging, and their results do not seem to justify a repetition of the experiment. It has been alleged that cases have recovered under this

line of treatment, but it is most likely that the cases where it was adopted were not those affected with true tetanus at all, or else the result followed from the administration of other constitutional remedies, and that nerve stretching neither did harm nor good in the case. It certainly seems contrary to all physiological reasoning to understand how nerve stretching could affect the spinal cord or nerves injured, except to irritate them still more, and increase the severity of the disease. The operation of nerve stretching is thus performed:—An incision about two inches long is made with a sharp scalpel over the course of the nerve supposed to be the medium of the irritation from the injured part to the spinal centre, when the nerve is laid bare and plainly discernible. The nerve is then grasped with a forceps, and first, it is forcibly stretched and pulled from its origin, and secondly, it is firmly pulled and stretched from its distribution. After this is done, the incision is closed again, and the parts brought together with sutures and plaster. This is the way the operation is performed, and how the proceedings can influence recovery in tetanus I am at a loss to understand; and I have no hesitation in saying that this mode of treatment for this disease is, in my opinion, most unsurgical and unphysiological.

Constitutional Treatment.—Very many remedies have been recommended from time to time, among which may be mentioned Indian hemp, chloroform, ether, opium, tobacco, quinine, aconite, stimulants, mercury, bleeding, cold effusion, ice-bags, purgatives, turpentine, belladonna, atropine, curara, calabar bean, conium, chloral, alcohol, bromide of potassium, counter irritants, and morphia. In a very practical analysis, by Dr. D. W. Zandell, of Louisville, (a) of a number of cases of tetanus treated by the various remedies above mentioned, he comes to the following conclusions:—"Recoveries from traumatic tetanus have been usually in cases in which the disease occurs subsequent to nine days after the injury. That when the symptoms last fourteen days recovery is the rule, and death the exception, apparently independent of the treatment. That chloroform up to this time has yielded the largest percentage of cures in acute tetanus. That the true test of a remedy for tetanus is its influence on the history of the disease. Does it cure cases in which the disease has set in previous to the ninth day? Does it fail in cases whose duration exceeds fourteen days? And that no agent tried by these tests has yet established its claims as a true remedy for tetanus."

Dr. Hammond mentioned three successful cases of traumatic tetanus occurring in his practice. They were all treated by canabis indica, and the persistent application of ice to the spine. In the first case it was traumatic, and ensued two weeks after a wound of the foot by a nail. The second was also traumatic and acute, that is, making its appearance nine days after the injury, which was caused by an ice-pick being accidentally thrust through the hand. The third case was that of a musician who injured his thumb with a splinter from the stock of a rifle. The first evidence of the tetanus appeared on the twelfth day. When the disease set in he had violent spasms, and opisthotonos was well marked. He was treated with extract of canabis indica (Squire's) in doses of half-a-grain every two hours, and kept up the application of ice to the spine continuously for six days. At the end of a week the canabis indica was omitted for a day, but the spasms became more frequent and severe. It was resumed as before, and on the twenty-fifth day it was left off altogether, the patient being convalescent.

Hammond also states, as his opinion, that whatever internal medication be adopted, the application of ice to the spine is a measure which should always form a feature in the treatment.

Now, the various remedies and plans enumerated, 1

(a) *American Practitioner*, September, 1870, p. 152.

think they may be placed under either of four practical heads, viz., the *purgative* plan, the *sedative*, the *antidotal*, and the *counter-irritant*. If purgatives are given, the best are croton oil, turpentine, or castor oil—two drops of the first-named with or without an enema; of castor oil and turpentine, ℥j. of each administered. The sedative treatment consists chiefly in the use of the cold douche applied to the whole of the body, or Chapman's ice-bag applied along the spine, and the internal administration of opium, tobacco, conium, henbane or Indian hemp. Such doses of these drugs should be given until the patient has been brought fully under their influence, and such should be administered in a fluid form if possible. The antidotal plan has much to recommend it, and consists in the exhibition of medicines whose effects act antagonistically to the effects of tetanus, and thereby diminish the function of the spinal cord in such a way as to either allay or prevent the muscular spasm. Alcohol, aconite, strychnia, and tobacco may have such an effect, and cases suitable for such a line of treatment may frequently present themselves. The counter-irritant plan consists in the application of blisters along the whole length of the spine, and the use of electricity. I mention this plan as it has been enumerated among various lines of treatment, but I do not at all place any confidence in it.

As regards my own views regarding the treatment of this important disease, I firmly believe that prevention is better than cure. If a case presented itself to me where there was an injury that I reasonably suspected tetanus might follow, or was known to follow, I would at once put the patient on a preventive line of treatment. I would attend to the state of the wound or injury. I would give a mixture containing—

R. Bromidi potassium, ℥ij;
Glycerin, ℥ij;
Aqua camph., āā ℥viii.

Two tablespoonfuls three times a day.

I would also administer the *anti-tetanic pill*, which contains—

R. Calomelanos, gr. xij;
Pulv. ipecac., gr. xij;
Pulv. antimoniaialis, gr. xij;
Opii, gr. iij;
Extract aloe, gr. xxiv.

Fiat massa—divide in twelve pills, one pill to be administered three times a day.

After this treatment had been continued for at least a fortnight, and nothing unusual had occurred, I should then probably stop it.

Suppose, however, that a *bonâ fide* case of tetanus presented itself to me. I would carry out the following régime, and place more dependence on it than any other plan I have seen adopted:—First, I would clear out the bowels with a good turpentine enema, after which I would place the patient in a darkened room, with carpeted floor, free from all noise or currents of air. I would apply Chapman's ice-bag to the spine. When the spasms came on I would administer chloroform until I had brought the patient fully under its influence. I would also administer it from time to time before the spasms came on. I would also give extract of Indian hemp, in doses of half-a-grain, every two hours.

In addition to this I would administer a moderate quantity of stimulants and beef-tea, and if these could not be taken by the mouth, I should give them by the rectum. With perfect rest, quietness, and freedom from currents of air, the sufferer is placed in the best position to withstand the exhaustion which takes place in the chronic form of the disease.

Sir Thomas Watson remarks:—"In all cases, there being no special indication to the contrary, I should be more disposed to administer wine in large quantities, and nourishment, than any particular drug."

Where the teeth are firmly clenched together it has been recommended to have two or three pulled out, so

as to make a space for the nozzle of a feeding cup. Also where spasm of the glottis is supposed to be the real cause of death, tracheotomy has been recommended to be performed, in order to anticipate such a termination. Perroud, of Lyons, has employed successfully the application of ether spray to the spine. Demarquay has used the hot-air bath. Dr. J. Thompson Hague, of the Zanzibar Military Hospital, has reported some successful cases which occurred among negroes treated by the subcutaneous injection, at repeated intervals, of one-sixth of a grain of extractum physostigmatis (calabar bean). Drs. E. Watson, of Glasgow, and Fraser, of Edinburgh, use calabar bean in one-grain doses, or five drops of the tincture, and have been successful with this treatment in some cases.

From what has been said it is clearly evident that, in the present state of our knowledge, there is no one remedy or plan on which we can rely with certainty for the cure of this very fatal malady, and I would strongly recommend, with the greatest confidence, that far more hope may be entertained in using remedies to rather prevent its recurrence, than the possibility of staying its progress where the disease has actually set in.

ON THE EARLY TREATMENT OF PROSTATIC OBSTRUCTION. (a)

By REGINALD HARRISON, F.R.C.S.,
Surgeon to the Liverpool Royal Infirmary.

It may be generally stated that of males who have passed fifty-five years of age, about one-third sooner or later suffer enlargement of the prostate; of these about one-half suffer therefrom, though so long as micturition is efficiently and painlessly performed, there are seldom grounds for complaint.

It is exceedingly interesting, as indicating how relief may be afforded, to analyse the cases where the prostate is large but does not obstruct; there are at least two conditions explanatory of non-interference with micturition under these circumstances.

First, where the hypertrophy is towards the rectum and the relations of the prostatic urethra are not altered; and second, where the hypertrophied gland is lobulated and channels are left between the masses along which urine flows without interruption. A careful consideration of these conditions has suggested that they are capable of artificial production to a useful extent.

The teaching of the present day is, however, to the effect that mechanical treatment is not to be employed until either retention occurs or the bladder becomes inflamed, then such means may be resorted to. It was asked why the same treatment should not be applied as in the case of urethral stricture. The objection generally advanced is that irritation will be produced. It was urged that there was no evidence in support of this objection. On the contrary, the prostate was about the most long-suffering organ in the body, and though it was subjected to a great variety of mechanical expedients, in lithotomy and other operations, it rarely became inflamed. It might just as well be said that because strictures were found occasionally to be exceedingly irritable, treatment was to be postponed until retention of urine or cystitis were provoked. But if intolerance to early mechanical treatment were proved, it was only postponing the day until the necessity was greater and the difficulty more apparent. If there was danger of irritating the prostate, it was none the less because its size was larger.

With the view of obtaining similar conditions to those occurring naturally in large prostates, where there is no interference with micturition, a mode of treatment with specially-adapted bougies was described. The instruments are gum-elastic, two to four inches longer in the stem than

(a) Abstract of Paper read at the Medical Society of London, March 13th, 1882.

usual, with an expanded portion an inch from the tip, which is made to enter the bladder. In this way the prostatic urethra is subjected to pressure on the insertion and withdrawal of the instrument.

As a rule, if dilatation is not too rapidly proceeded with, no irritation is aroused. On the contrary, greater toleration of urine follows, owing to the ease and completeness with which the bladder is then emptied.

In a few persons it became necessary to establish a state of instrumental toleration, the frequency for doing this, as a rule, depending more on the manipulator than on the instrument. In some individuals intolerance of urethral interference was entirely due to the condition of the urine. Such sensitiveness had been traced to the presence of uric acid in unnatural quantities and form. On the correction of this, patients previously intolerant of instruments were found capable of undergoing the necessary mechanical treatment with the greatest advantage.

In advocating the early treatment of prostatic obstruction by the means referred to, the author had already had sufficient proof of its efficacy. He had demonstrated that the regular use of the dilators was capable of so moulding the enlargement as to prevent obstruction. Cases were under observation where the symptoms indicated that an impediment to micturition was commencing to form. Such patients in this way regained the power they were beginning to lose. In bringing forward his views on the subject, Mr. Harrison did so with the feeling that little had been yet done towards preventing the progressive development of a condition which was often followed by very distressing, and sometimes embarrassing, results—results which we knew of and stood by to palliate, though we had hitherto been helpless in preventing them.

Clinical Records.

EAST LONDON CHILDREN'S HOSPITAL.

A Case of Tubercle of the Brain—Death—Autopsy.

Under the care of Dr. EUSTACE SMITH.

Reported by Mr. SIDNEY DAVIES, B.A., M.R.C.S., Clinical Assistant.

PERCY GRAY, *æt.* 6 months, was admitted into the hospital on Jan. 12th. The mother, who brought the child, stated that she and the father were healthy, and that they had had four children, one of whom died of diarrhoea, and another of whooping-cough and bronchitis, both at an early age. The remaining child suffered from enlarged tonsils and "weak throat." The patient had been fed on cow's milk, water and sugar, owing to the mother's milk being deficient. When ten days old the nurse had given it some sour milk, which brought on diarrhoea with attacks of retching. For the last month the child had been wasting; it had coughed for a week, and the cough was getting worse. It had had no convulsions. When one week old an eruption had appeared on the buttock and spread to the abdomen, and it had the thrush in its mouth; both lasted six weeks.

When first seen, the child was very pale, with a waxy, yellow complexion. The bridge of the nose was not depressed, but rather broad, and there were no scars about the mouth nor about the anus. When the child cried, the mouth was drawn to the left side; also the left nasal line was deeper than the right.

On percussing the chest no dulness was found at the back, but the upper third of the left front, excluding the acromial angle, was dull, and there was tubular breathing over the same area; while in the acromial angle the breathing was high pitched and bronchial, and there was some fine bubbling with a deep inspiration.

The spleen was two fingers' breadth below the ribs, and the edge was firm and sharp. The liver was one finger's breadth below the ribs. Temp. 100°.

The child was ordered a diet of milk, barley-water, and Mellin's food, and the following prescription:—

Mist. ferri alk., ℥j. T. d. s.
Pulv. rhei et sodæ, gr. vi;
Pulv. cret. aromat., gr. x. O. m.

The following notes were taken of the patient's subsequent condition and progress:—

17th.—The child keeps its head retracted when in bed; when sat up the head is not drawn much back. Voice very hoarse. Fontanelle large. Right eye more open than left. When the child cries the lines on the left side of the face are more marked than on the right. The eyebrows contract equally on both sides. Pupils equal. No squint observed.

Post-cervical glands enlarged; some enlarged glands in axilla; none in groin. Motions loose, very slimy. Temp. last night, 102°; this morning normal.

Ordered yolk of egg, veal broth, barley water, and Mellin's food, to be given as a varied diet, and—

Liq. hyd. perchl., ℥xx.;
Tr. opii, ℥ss.;
Glycerini, ℥xx.;
Aq. ad, ʒj. T. d. s.

20th.—Child much quieter since taking the medicine. Has been troubled with vomiting, which ceased when the Mellin's food was left off.

Head still retracted, and muscles of neck rigid as child lies in bed. Occasional tremulous movements of right arm and leg, most marked when it attempts voluntary movements. Thumbs not twisted in. Abdomen is not retracted, nor are its walls specially inelastic. Frequent hard hacking cough. No laryngeal spasm. Is said to choke when taking medicine. Takes bottle with perfect ease. Still very hoarse.

Physical Signs.—Dulness upper third of left back; respiration weak and blowing; vocal resonance increased. Slight dulness at right supra-scapular fossa; respiration still bronchial, with increased resonance of laryngeal sounds. Large clicks about back on both sides. There is some want of expression on the right side of the face. Right eye is more open than left. Left brow more contracted than right. When the child cries the left corner of the mouth is drawn up. Left nasal line is more marked than the right. Left pupil rather smaller than right; both pupils contract well with light. Temp. 101·8° last night; 99° this morning.

21st.—Child lying asleep on right side, with head retracted as before. Is said to sleep better on the right side. Pulse about 175, almost imperceptible, but apparently regular; respiration 52, regular. Thumbs not turned in. When the child is awakened, and crying, the mouth is much drawn to the left side; left eye is more closed than the right, and left pupil decidedly smaller than right. Brows equally contracted.

23rd.—Child lying asleep on the right side, with head retracted, but the posterior cervical muscles less rigid than before. Both eyes closed; mouth open; pulse 140; respiration 60, regular. Face very pale. Fontanelle slightly depressed, pulsates. Skin of abdomen not markedly inelastic. Thumbs slightly inverted. Muscles of limbs relaxed when asleep, but rigid when the child is awake. It is reported that when the child was washed this morning he had convulsive retractions of the right arm and leg. He slept badly. Temp. 102°; last night 102·2°.

24th.—Face livid, very pale. Head retracted. Eyes turned upwards, and to the left; pupils equal. Abdomen not retracted. Respiration regular. Some rigidity of the left elbow, wrist, and fingers. Thumbs twisted in. Less rigidity of right elbow than left, but right fingers are equally as rigid as the left. Child often keeps little and ring fingers extended. Has not been sick to-day. Motions very loose. Fontanelle level. To-day, when the child is fed, it lets the fluid run out of its mouth, and coughs with a clanging sound. Respirations laborious, with much recession of soft parts at each inspiration. Child lies unconscious, but when moved looked sensible for a moment, though it took no notice of an object passed before its eyes.

Physical Signs.—Some dulness all left side, back and front; heart's apex just below nipple. Respiration blowing and high pitched; occasional large clicks; vocal resonance increased. Much increase of resistance. Chest punctured with exploring trochar in the 5th space; no fluid found. Child's breath smells putrid. Face more symmetrical than before; both sides seem to move equally well. No Stokes' type of breathing. Temp. 102·6°; 100·6° last night.

25th.—Head more retracted than ever. Breathing regular. Thumbs turned in. Toes flexed. Winks when conjunctiva is touched. Both elbows rather stiff. Child very pale; can't swallow. Appears conscious when waked. Mouth drawn a little to one side; lower jaw retracted. Temp. 100·5° last night; 101·6° this morning.

The child died on the 25th, at 5 p.m.

Autopsy, performed twenty-four hours after death.—Superficial ulceration round anus and scrotum, with post-mortem discolouration all over back, and partly in front. Cranium removed with difficulty, lacerating the left middle lobe of the brain, from which spurted out about an ounce of clear fluid. Some venous congestion of the upper surface of the cerebrum, chiefly on the left side. Puncta cruenta not larger than usual. On the under surface of the right frontal lobe small lymph deposits, covering a surface as large as a crown-piece. Right Sylvian fissure closed by dense, tough, gelatinous lymph, gluing the two sides together. Otherwise, there was no lymph at the base of the brain, nor any granulations along the vessels. Membranes on the whole smooth and glistening. Lateral ventricles normal. At the left lower half of the pons, nearer the lower and anterior surface, was found on section a caseous mass (tubercle), the size of a cherry-stone, soft in the centre, but entirely surrounded by brain tissue. Beneath the left crus cerebri was another lump of the same matter, soft in the centre, the size of a small marble, surrounded by pia mater, and attached by a stalk of the same membrane to the top of the medulla. No ante-mortem clot found in the venous sinuses. Two or three ounces of fluid in the left pleural cavity. Some lymph on the visceral pleura and opacity of the costal pleura. Adhesions at left apex. A caseous mass, the size of a small marble, on the surface of the lower lobe of the left lung. The middle and lower lobes in a state resembling grey hepatization, but less friable. Upper lobe partly solidified, containing some small cavities. Some emphysema of right lung, and some solidification at base. A mass of enlarged bronchial glands about roots of lungs in various stages of degeneration. Other organs not examined.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

FRIDAY, MARCH 10TH.

The President, JOSEPH LISTER, F.R.S., in the Chair.

CHIMNEY SWEET'S CANCER.

Mr. GEO. LAWSON brought before the Society a chimney sweep, upon whom he had operated for chimney sweep's cancer in the axilla. The patient had had the disease twice removed, but it recurred after each operation. He was admitted into the Middlesex Hospital last November. His condition then was:—In the right axilla there was a wound about two inches long, with hard ragged edges, and from this there was a sanious fetid discharge. Through this wound a probe could be passed in all directions beneath the pectoral muscle, where there was evidently a large epithelial ulcer. The patient was anxious for an operation, but as it was clear that, owing to the rigid state of the pectoral over the ulcer, that the mere excision of the growth would not prove satisfactory, Mr. Lawson obtained the sanction of the patient to amputate the arm at the shoulder-joint if, in the course of the operation, he thought it advisable. On November 24, the patient having been placed under ether, a knife was passed into the wound in the axilla, and the pectoralis major divided. A large epitheliomatous ulcer was then exposed. This was dissected away, but as the disease had encroached on the artery close to the axilla, Mr. Lawson felt that if he stopped here the operation would be useless. He therefore tied the axillary artery just below the edge of the lesser pectoral muscle, where the artery and tissues were healthy, and as the wound was very large, he amputated the arm at the shoulder-joint, and brought the flap, which he had made of skin and muscle, on to the chest. In some remarks at the close of the paper, Mr. Lawson said that the reasons which induced him to amputate the arm at the shoulder-joint were:—First, to obtain sufficient skin to cover the wound caused by the excision of the epithelioma and the division of the pectoral muscle; and next, to prevent the formation of a free collateral supply of blood to the region from which the epithelioma had been removed.

The PRESIDENT asked if the epitheliomatous growth was

in any respect remarkable, or distinguished from ordinary growths of a similar kind; and

Mr. LAWSON replied that it was not, to his knowledge; but he did not see the case during its early stages.

Mr. J. CROFT inquired whether, in dissecting the amputated arm, the sheaths of the axillary artery, or vein, or cords (particularly the inner) of the brachial plexus had been found infiltrated.

Mr. LAWSON answered that the artery was involved in this way.

The PRESIDENT remarked that amputation was the proper course to adopt in the case, and expressed a hope for the patient's recovery.

Mr. HOWARD MARSH read a case of

ANEURISM OF THE LEFT AXILLARY—LIGATURE OF THE SUBCLAVIAN—RUPTURE OF THE SAC—AMPUTATION OF THE SHOULDER-JOINT—RECOVERY.

The patient was a carman, *æt.* 32. He had never had syphilis or any serious illness. Eight weeks before admission he found a small pulsating swelling in the arm-pit. This rapidly increased, and when he came to the hospital measured nineteen inches over its most prominent part. There was great oedema of the whole limb. No pulse could be felt at the wrist. After the patient had been at rest for three days in bed, the subclavian was tied, under the carbolic spray, with a silk ligature, the ends of which were cut short. The case progressed favourably for three or four days, but then the swelling gradually increased in size, and on the 17th day hemorrhage occurred from the sac. This having recurred on the 18th day, the swelling was laid open with the object of tying which ever proved to be the bleeding end of the artery. As, however, a gush of arterial blood immediately occurred, and as the patient was still in a very exhausted state, it was thought best to amputate at once at the shoulder-joint. The patient made a favourable recovery. The author remarked that the cause of the aneurism was probably a small rupture of the coats of the axillary artery resulting from a strain. The case was a good illustration of the usual features of aneurism in the axilla, in respect to its rapid increase, the large size the swelling may attain, and the tendency of the sac to rupture. Ligature of the subclavian—the method of treatment most often successful—seemed to offer the best prospect of cure. It failed through the free establishment of the collateral circulation. Had the patient been in a less exhausted condition the limb might perhaps have been saved by Syme's operation, even when the sac had given way; but, weak as he was, amputation seemed the safer expedient. The silk ligature, after it was thrown off, travelled toward the surface, and could at one time be felt close beneath the skin, and a small shred was discharged through the wound. How it was afterwards disposed of was not known. It never, however, was observed to escape externally. The silk ligature, the author thought, was unsafe, as it was apt to act as a foreign body, and so to provoke a dangerous process of ulceration in the neighbourhood of the artery. He should, on any similar occasion, employ the kangaroo-tendon ligature, which so far as present experience has shown, is perhaps the most reliable form now in use.

Mr. GOLDING BIRD wished to know if silk soaked in carbolic oil had been preferred to that soaked in carbolised wax for any particular reason. He himself always preferred the latter medium for disinfecting the ligature. He did not quite comprehend whether Mr. Marsh had described the removal of a portion of the ligature by the house-surgeon; and at the suggestion of the President,

Mr. HOWARD MARSH explained that the artery had been cut through by the loop of the ligature, which subsequently travelled toward the surface, and a shred of which only was removed by the house-surgeon. He was ignorant of the fate of the bulk of the ligature.

Mr. CHRISTOPHER HEATH considered that, from the account of the case on admission, it was probable the aneurism had then given way. In such circumstances ligature of the subclavian could not be expected to produce a cure. When doubt was experienced on this point, the course followed in Syme's classical case was the most profitable proceeding, the subclavian being kept, meanwhile, well under control.

Mr. BARWELL agreed with Mr. Heath as to the probable rupture of the aneurism. Signs of inflammation were not,

he thought, well marked from the description. He considered that danger from hæmorrhage was much lessened by the employment of animal ligatures.

Mr. J. H. MORGAN suggested that pathological details of the condition of the amputated limb would be desirable and instructive.

Mr. LISTER said the case was interesting in regard both to treatment and to the question of ligatures. He, too, considered that the sac had given way before the admission of the patient into hospital; it was, in other words, a diffuse aneurism. He did not, however, believe that in all such cases ligature of the main artery would be necessarily useless. In two instances he had operated for the relief of diffuse popliteal aneurism by ligature of the femoral artery. In one the tumour spread half-way up the thigh, and in the other to the level of Poupart's ligament, and in both a successful result was obtained. Every case of this kind required to be considered and treated with respect to the special circumstances surrounding it. He was much interested at hearing of another case in which a silk ligature had made its way to the surface, since it was this tendency on the part of silk that first induced him to make a trial of catgut as a substitute for it. He would now, if about to employ silk, steep it first in a watery solution of carbolic acid, this being by far the most effectual way of securing its being made aseptic throughout, and at the same time affording greater certainty of the knot holding. Animal ligatures, however, were much to be preferred. When, more than a year ago, he had described the mode he adopted for preparing these ligatures, he regarded his conclusions as final, but soon after he had been disappointed to find that the chromic catgut ligatures differed widely. Those that were *thicker* were more prone to speedy infiltration as distinguished from erosion; and further, he discovered that catgut manufactured without the use of sulphur in the process was even worse in this respect. A series of experiments were then made by steeping catgut in sulphurous acid, by which means a more efficient article was obtained, the process finally adopted for its preparation being the following:—Leave for twelve hours in a one per cent. solution of chromic acid, and next, for the same time, in a solution of sulphurous acid, B.P. strength. The advantages catgut so prepared possessed were several and important. It did not undergo surface infiltration. Even after remaining for three weeks in a puriform medium it retained its full power of resistance. It might be stored dry, needing only to be dipped in a watery solution of carbolic acid just before being used, thus avoiding the necessity for storing in carbolic oil.

Mr. HOWARD MARSH reminded the Society that since the date referred to in his paper as that on which the silk had been used, considerable discussion on ligatures had ensued. He employed it chiefly because it was at that time much vaunted by successful ovariologists. In reply to Mr. Heath's remarks he had to urge that when the patient was first admitted he was in a most exhausted condition, and some immediate operation was called for, which should be palliative, and enable the patient to regain strength to withstand the shock of more serious procedures. Moreover, ligature of the subclavian had certainly succeeded in former cases. He agreed, however, that under ordinary circumstances, Symes' operation would be advisable. In proof that the subclavian could not always be controlled by pressure merely, he referred to a case in which two years ago he amputated at the shoulder-joint. The artery was being compressed by an assistant of unusual strength, but, notwithstanding, the fingers of the latter were actually lifted off by the pressure and changes of position induced by the movement of the limb during the operation. He (Mr. Marsh) then determined, in view of the dangers incurred in this case, always to cut down and expose the subclavian in any similar operation. In the case under discussion when the vessel (axillary) was tied above, it was healthy, but the arm was too much disorganised to afford any valuable pathological information.

MYXŒDEMA IMPROVING UNDER TREATMENT.

DR. MAHOMED showed a case occurring in a married woman, æt. 30. Her family history was good. She had been married twelve years, and had had seven children, the youngest child eight months old. The symptoms of her disease commenced towards the end of her first pregnancy. She had the usual symptoms of the disease, and her appear-

ance was very characteristic. When first seen, there was great swelling of the lower eyelids, which hung like bags containing fluid; her face was generally swollen, lips bluish, cheeks pink; hands were hard, swollen, brawny, and stiff—so that her movements were awkward, and her sensation impaired. There was no pitting on pressure of the affected parts; the lower extremities were not affected. Speech was slow and laborious, as usual in this disease. Her chief complaint was pain at the top of the head, worse towards evening and at night. The urine was not albuminous; the impulse of the heart was not perceptible; pulse small, artery apparently contracted, so that at first no satisfactory tracing could be obtained. During the first fortnight no change in her symptoms was perceptible; after that she was treated by 1-50th of a drop of nitro-glycerine, and from this time she rapidly improved. The headache immediately disappeared. In a fortnight the appearance of extreme swelling below the eyes had very greatly diminished; her hands were supple, much softer, her gloves being too large for her; she talked quicker. The treatment had been assisted during the last week by severe purging. A trace of albumen was found in her urine on two occasions. Her pulse tracing when her arteries had been dilated by nitro-glycerine showed an increase of pressure and prolongation of systole. The improvement in her condition has been frequently remarked upon by her friends and all who have seen her at the hospital. She has now been under treatment about two months, and the skin of her hands is quite loose, and almost natural. Her face, though much improved, is still characteristic of the disease. A photograph taken on February 20th was exhibited. Dr. Mahomed treated her with nitro-glycerine with the intention of relaxing her arteries, thus reducing, to some extent, the arterial pressure, and increasing the rapidity of her capillary circulation. Severe purgatives, which, she said, afforded her great relief, were administered with the same object.

DR. CAVAFY thought the improvement should be described as occurring *during* rather than *under* treatment; it was undoubtedly true that such variations did occur in myxœdematous patients. In December last he had recorded before the Society two cases, in one of which the swelling of the fingers was much reduced, and in the other improvement was observed very similar to that seen in Dr. Mahomed's patient. A third case within his own knowledge, that of a gentleman under the care of Dr. Bennett, had likewise shown marked signs of improvement; and a fourth example, in this case recovery being all but complete, had formed the subject of a special lecture by Charcot. This last patient had been treated by removal to a warm climate, with milk diet and sulphur baths. His own cases had been treated, the first with ergot, the second with strychnine. Dr. Bennett's treatment was chiefly to administer iodide of potassium, the patient having, at some time, suffered from syphilis. Thus, no two modes of treatment agreed, and in all the cases mentioned, the symptoms, notwithstanding, improved, so that the favourable change could hardly be attributed to treatment as a cause. He, Dr. Cavafy, believed climatic influences had much to do with variations in the condition of cases of myxœdema.

DR. FRANCIS TAYLER mentioned that he had under his care a case of myxœdema in which improvement had taken place, the œdema being much reduced. Jaborandi was the drug employed in the treatment of it.

DR. HADDEN advocated the employment of nitrite of amyl in these cases.

MR. WARRINGTON HAWARD added the history of a man in whom the œdema, &c., of myxœdema was much reduced while under treatment. He was a syphilitic, and injections of morphia had been necessary on account of pain. After leaving the hospital and engaging in active pursuits, the mental faculties, previously dulled, had undergone much improvement.

MR. LISTER thought it remarkable that so many cases of improvement should be brought forward. He failed to understand the theoretical grounds on which Dr. Mahomed recommended his plan of treatment, or that the œdema could be controlled by arterial relaxation. This was essentially opposed to Dr. Cavafy's method, in which constriction of the arteries was aided by the administration of ergot.

DR. MAHOMED urged that the fact of the onset and disappearance of œdema in myxœdema proved that it was not a permanent form of degeneration. He considered the resemblance of myxœdema to chronic Bright's disease was pointed by the remarks of Dr. Cavafy, and others, and by the fact that Charcot's treatment of patients suffering from myxœdema was

practically that adopted for the latter form of illness. When the powders he prescribed, and which produced purging, were continually used, the condition of his patient was much improved. Dr. Mahomed concluded by explaining that he had many reasons for assuming that relaxation of their walls did not necessarily induce increased pressure in the capillaries, but that these reasons could only be stated at considerable length.

France.

[FROM OUR SPECIAL CORRESPONDENT.]

MICROSCOPICAL INSPECTION OF AMERICAN PORK.—Some time ago the Government requested the Académie de Médecine to give its opinion on the necessity or otherwise of inspecting microscopically all the pork that comes from America, in order to detect any portion that should contain parasites (*trichina*) with a view to its immediate confiscation. Last week that learned body, through the Commission delegated to examine the question, decided that inspection was not necessary, since the meat when sufficiently cooked completely destroyed the parasites, and that it would be sufficient to warn the public against the possible danger of using pork raw or half-cooked.

M. MONOD, at the meeting of the Société de Chirurgie, compared the results given by operations practised after the old method and those in which antiseptics were used. These latter gave a mortality of 4 per cent, while that of the former was 17 per cent. The greater number of deaths were due to pyæmia and septicæmia. If abstraction were made of the deaths attributed to these two last affections the result would be the same in both methods, viz., 3 per cent. Accordingly, the introduction of antiseptics in surgical practice has tended to lessen very materially the chances of such complications as septicæmia and pyæmia. **M. Verneuil** avowed that heretofore pyæmia was a common malady in hospitals, and against which surgeons were powerless, but since the employment of antiseptics the disease has disappeared.

TAPPING THE PERICARDIUM.—**M. Rendu** communicated a very interesting observation of a case of pericardial effusion treated by puncture to the Société Médicale des Hôpitaux. A young man was attacked with dry pericarditis, the result of a chill. Soon after entering the hospital all the signs of effusion appeared, and in less than twenty-four hours the pericardium became considerably distended. The patient had frequent attacks of dyspnoea, and soon cyanosis commenced. It was at this stage that **M. Rendu** decided on tapping the pericardium. The puncture was made an inch and a-half below the left nipple, and an exit was given to a considerable quantity of liquid, to the great relief of the patient. A few days afterwards he left the hospital cured. **M. Labouleaue** had in his service a patient also suffering from effusion into the pericardium, but complicated by pleurisy. Thoracentesis was practised with success, but he hesitated to tap the pericardium. **M. Paul** declared that paracentesis of the pericardium was an operation before which one generally hesitated, as much on account of the difficulties of the diagnosis as on that of the almost constant failure of the operation. When the patient was young and the disease was fully developed, one might attempt the operation. There was but one region where puncture might be attended with danger, and that was the part corresponding to the heart's apex, which should be carefully examined.

DIVORCE AND INSANITY.—**M. Charcot**, of the Salpêtrière

was examined before the Parliamentary Commission of Divorce as to whether insanity should be considered a sufficient cause for divorce. The learned professor expressed the opinion that in no case was it possible to determine in an absolute manner on the incurability of insanity unless where there was general paralysis. In this case the patient dies in a period not exceeding five years; consequently one might very well wait for the expiration of that time, which effected a natural solution in the situation of the patient. The legal delay exacted by the process of obtaining a divorce would thus be hardly exceeded. The Commission accordingly rejected insanity as a cause of divorce.

TREATMENT OF DIPHTHERIA IN CHILDREN.—**M. Jules Simon**, of the Hôpital des Enfants Malades, gives the following as his treatment for diphtheria:—Internally, tonics in every form, alcohol in large doses, strong coffee, beef-tea, &c. Besides, he orders every two hours three or four drops of the tincture of iron in a little water, never in milk. If the child were rather big he gave a drachm or so in divided doses during the day of the following mixture:—Copaiba, ℥j.; cubebs, ℥ij.; carbonate of iron, ℥j.; bismuth, q. s. Locally, he applied citron-juice, or dilute citric acid, or tannin, or even perchloride of iron in water every two or three hours. Nitrate of silver should never be used, nor should hydrochloric acid. Besides the above applications, the throat should be irrigated with a weak solution of phenic acid three or four times a day. There was another resource to which he had frequently recourse, but always with a certain reserve, and that was the administration of vomitives. Ipecacuanha might be given at the commencement, when there existed a good deal of mucosity about the larynx, or when in the later stages the false membranes were inclined to detach themselves. The chamber of the patient should be kept warm, and the atmosphere rendered humid by the spray of phenic acid.

METHYLTRIETHYLSTIBONIUM.—A French chemist endeavoured to astonish the Société de Biologie last week by communicating to that body his discovery of a new medicinal agent which acts like curare. The reporter did not say that the meeting went into hysterics and suddenly collapsed when the name of the drug was pronounced, but it would be perfectly legitimate to infer it. **M. Rabuteau** christened his discovery iodide of methyltriethylstibonium. It would look beautiful on a prescription.

At the ordinary meeting of the Sanitary Institute, held on Wednesday last, **Dr. A. Carpenter** in the chair, the prize of £200 for an essay on "The Range of Hereditary Tendencies in Health and Disease" was presented by the **Rev. E. Wyatt Edgell, B.A.**, to **Mr. G. Gaskoin, M.R.C.S.**, Surgeon to the British Hospital for Skin Diseases.

THE annual rates of mortality last week in the principal large towns of the United Kingdom, per 1,000 of their population, were—Hull, Derby, Leicester 19; Edinburgh, Newcastle-on-Tyne, Portsmouth, Birkenhead, Cardiff, Birmingham 20; Leeds, Norwich, Salford, Bristol, Sunderland 22; Sheffield, Bolton 23; London, Glasgow 24; Bradford, Halifax, Wolverhampton 25; Preston, Huddersfield 26; Plymouth, Manchester 28; Liverpool 29; Nottingham, Oldham 31; Brighton 33; Dublin 35; Blackburn 38.

WEDNESDAY, MARCH 15, 1882.

THE CREMATION QUESTION.

PROMINENCE has during the past week been given to the cremation question by an occurrence which places it in a new and somewhat curious light. The executors of a gentleman named Crookenden were sued for payment of the sum of £321 by a lady, who claimed this amount as expenses incurred in carrying out the wish of the deceased, that his remains should be disposed of by cremation. The case came before Mr. Justice Kay, in the Chancery Division of the High Court of Justice, and was decided in favour of the defendants, costs also being given against the plaintiff, Miss Williams. It transpired during the hearing of the suit that a promise had been given by Miss Williams during the life of Mr. Crookenden, to carry out his wish to be burnt after death, and specific directions were given in his will for the payment of such expenses as might be incurred by Miss Williams in fulfilling the request conveyed to her in a private letter mentioned in the codicil. The testator, however, was buried in Brompton Cemetery, and some months afterwards Miss Williams applied to the Home Secretary for permission to remove the body. This was, after a first refusal, accorded, on the understanding that such removal was to be allowed for reburial of the corpse in a Welsh churchyard, and on the express condition that it should not be cremated. Having thus obtained her friend's remains, Miss Williams forthwith carried them to Italy, and there had them burnt.

The legal aspects of the case were clear, and in the present state of English law, could not be gainsaid. A

testator has no power of disposing of his own body after death, his executors being its sole guardians, with legal rights to resist every and any claim to its possession from other quarters. That this should be so is undoubtedly hard upon individuals, who may justly complain of an inability to decide in what manner their remains shall be dealt with; and in this particular instance our sympathies must certainly be with Miss Williams in her desire to carry out the emphatically expressed intentions of her deceased friend. Notwithstanding this, however, the fact that possession of the body was obtained by misrepresentations very properly entails such penalties as the adverse verdict ensures, while at the same time the impossibility that at present exists of any person willing that his death shall not be a cause of endangering public health opens up the gravest social considerations. There are very many people now alive who regard with feelings of the utmost abhorrence their future confinement to an earthen grave. Indeed, within the last few years there has sprung up in this country a strong and ever-increasing disgust against the harmful and unsanitary system of burial that obtains amongst us. Each year the growth of cities and towns is proving with the utmost certainty how, by-and-by, spots that are seats of constant noxious emanations proceeding from compact masses of decomposing bodies, will be covered with the dwelling places of a coming generation; and while every year the overgrown graveyards of suburban places are crowded yet more densely with the remnants of humanity, to an equal extent is the health of the whole surrounding neighbourhood being imperilled. For, as surely as the demand for more and more houses increases with the growth of population, so will the fringe of dwellings around large cemeteries creep closer and closer on to the boundaries of the dead. It needs but a glance at such neighbourhoods as Norwood, Honor Oak, or Nunhead, and comparison of the aspects presented by these places now with that they showed a dozen or twenty years ago, to see the deadly nature of the danger to be dreaded from this building around and about graveyards. Every house that is erected robs the neighbourhood of a portion of the open space which, at their creation, surrounded these burial grounds, and adds, moreover, another family to those already brought into too close relation with the dead. A decade or two ago this gave less cause for trouble than it does now, and less attention, too, was then paid, generally, to the preservation of health by attention to rules of hygiene. But now, a knowledge of the laws of life is not confined to the few who make such knowledge the basis of professional training; it is, rather, shared by every educated person, and with it has arisen a wholesome and laudable desire to conform to Nature's inviolable demands. Hence can be traced the widespread disinclination to burial after death on the part of intelligent thinkers, and the rapid growth of public opinion in favour of rational disposal of corpses by cremation. The legalisation of the practice must sooner or later become a pressing necessity, and the sooner it is brought about the earlier will the nation be freed from a danger that it is becoming painfully alive to.

The chief objection hitherto raised against the practice,

apart from those of a purely sentimental and untenable nature, is that it will tend, if generally adopted, to facilitate the concealment of crimes. This, however, is at best but a short-sighted view of the matter, for under simple and easily carried out regulations, it might easily be made the strongest protection against crime of the kind indulged in by poisoners, which is the principal danger complained of. There is no reason why, prior to cremation, a post-mortem examination of every body should not be made; and even though not followed in all cases, yet wherever occasion seemed to demand it, analysis of the contents of the stomach could be added, to make assurance doubly sure. The gain to science from such a proceeding cannot be too highly estimated. Post-mortem records teach many most important lessons; and when these are conducted on every person who dies, and the information thus obtained is scheduled by properly qualified officials, it is impossible to foresee the results to which it might lead. Attempts have hitherto been made in vain to legalise cremation in this country. As the law regarding burial now stands, however, there is little to recommend it to thinking men. It practically hinders all attempts by individuals to assist the progress of sanitary reform; it is unduly restrictive of the liberty of the subject in a matter that most gravely concerns himself; and, in our opinion, it imposes barriers of the most improper kind on a just and reasonable endeavour to promote the health of the people. We must admit, of course, that Miss Williams acted very wrongly in transgressing the law as she did by causing Mr. Crookenden's body to be cremated, in the face of the Home Secretary's refusal; but none the less it cannot fail to be a matter of regret that, in giving his refusal to a scientific disposal of a dead body, the Home Secretary was exercising a right that the law gives him power to exert. In spite of memorials bearing numerous signatures of high scientific and medical authorities, praying for a removal of the legal disabilities in respect to cremation, the introduction of this much-needed reform has been obstinately opposed; but it must ere long become a question of such universal interest that further prohibition will be impossible; and that time cannot too speedily arrive.

THE EDUCATIONAL REFORMS IN THE ROYAL COLLEGE OF SURGEONS OF IRELAND.

WE recently reported to our readers the fact that the President, Vice-President, and three Members of the Council of the Irish College of Surgeons had waited upon the Home Secretary at Westminster with reference to the authorisation by Government of the educational reforms which have been adopted by the College, and we noted the fact that, at the same time and place, a counter-deputation of obstructionists to these reforms had also had an interview with the same Minister. We abstained from exposing the *personnel* of this second demonstration, lest there might appear to be any personal element in the controversy. But it is no longer possible to be reticent, inasmuch as an entirely inaccurate paragraph—penned in glorification of the counter-deputation, and almost insulting in its reference to the delegates which represented the

College—has been published editorially in the *Lancet* of Feb. 25. This report speaks of the counter-deputation as "representing the views of a large number of influential Fellows," and of the College representatives as "Drs. A., B., C., D., and E." The matter has, however, been noticed in the last issue of the *Lancet* in the following letter by Dr. Jacob, which makes unnecessary any further reference to the subject by this journal:—

THE EDUCATIONAL REFORMS IN THE IRISH COLLEGE OF SURGEONS.

To the Editor of the *Lancet*.

SIR,—I regret to observe that your columns have been utilised by one or other of the two opponents of the new educational scheme of the Irish College of Surgeons to misrepresent the purpose and the importance of the two deputations which waited the week before last on the Home Secretary. The real truth is that the President, Vice-President, two ex-Presidents, and myself, a Councilor of the College, were deputed by the College Council to explain to the Minister that we wanted his approval of the annulling of certain bye-laws which are inconsistent with the scheme.

It is not true that the Home Secretary's sanction is necessary to the annulling of any bye-law of the College, but the Council, nevertheless, thought it inadvisable to put their new regulations in force until the responsible Minister has been informed of their intention to do so.

After this deputation had been received, as officially representing the College, two gentlemen were received as claiming to represent a body of Fellows opposed to the reform. It may, however, be doubted that they represented anyone but themselves, considering that after the most vigorous whipping of the Fellows, notwithstanding the most earnest importunity that they would accompany the counter-deputation, and after much boasting as to the importance of the coming demonstration against the new scheme, one Fellow, and one only, Mr. Ormsby, could be induced to follow the leader of the opposition. Driven to extremities to make a decent show before the Home Secretary, these two gentlemen drove about London entreating Fellows of the College there resident to join them in their interview, with the result that a naval surgeon, who was entirely ignorant of the contemplated reforms, was induced to go as far as the House of Commons, but declined to go further or to see the Home Secretary at all.

This, Mr. Editor, was the important deputation which the *Lancet* is used to announce before the profession. There is, indeed, now no party worthy of the name opposed to the contemplated reforms, the small band of Fellows who formerly resisted them having melted away since they had the opportunity of examining the new scheme for themselves. The merits or demerits of that scheme I shall not discuss with Mr. Ormsby. It is enough to say that it has been debated over and over again, line by line, by those at least as competent as Mr. Ormsby can be to judge of the value of the reforms and their effect on the College, and, by sweeping majorities, every successive point in it has been established.

All these statements I vouch for; and I therefore regret that so influential a journal as the *Lancet* should permit itself to be made use of for the dissemination of reports which are not accurate.

I am, Sir, yours, &c.,

ARCHIBALD H. JACOB, M.D. Dub., F.R.C.S.I.

Ely Place, Dublin, March, 1882.

THE "PARANGI DISEASE" OF CEYLON.

AN interesting Report on the disease or diseases so named has recently been prepared by Dr. Kynsey, prin-

principal civil medical officer of Ceylon. The very name given to the affections described sounds strange. It appears to be a corruption of the word *Farangi*, or *Feringee*, as the latter is pronounced in India; that the term thus represented was that by which the Portuguese were known in the island and mainland from the time of their early settlement on both; and that accordingly the full appellation *Farangi-lede* simply means Portuguese or foreign sickness. What is the precise nature of the sickness so called? Or are several distinct forms of disease united in the subject of Parangi? The latter appears to be the case, as, according to the report on the subject, it partakes of the nature of syphilis, to which are superadded characters of land scurvy, yaws, pellagra, scabies, tinea, impetigo, ecthyma, and other cutaneous maladies, lupus, leprosy, and scrofula. It appears to exist as an endemic in particular parts of the island, more especially in the Northern, North Central, and North-Western provinces. It was for some time believed that the disease owed its extensive prevalence to the practice of vaccination. Further inquiries, however, seem to show that no foundation really exists for this belief, as Parangi chiefly prevails in districts where, owing to its presence, vaccination cannot be carried on. The first mention of Parangi-lede occurred in 1548. It was then described as the Neapolitan disease, and the Portuguese disease. There appears to be little doubt that the word was then restricted to syphilis, which was first introduced into Asia in the sixteenth century, soon after its epidemic-like outbreak in Italy, when the army of Charles VIII. was besieging Naples. Previous to that date syphilis does not seem to have been known in India. The old Hindoo writers described various maladies of the genital organs; but in old Sanskrit there is no name for it, and in modern Sanskrit works it is called "Faringa Rôga," or Portuguese disease. When first described, namely, forty-three years after the landing of the Portuguese on the island of Ceylon, mercury was chiefly employed in its treatment. Sarsaparilla does not appear to have been used for the same purpose until considerably later, when Chinese traders to Goa, on the coast of Malabar, appear to have introduced the *Smilax Chinensis* as a drug for syphilis.

The views already formulated with regard to the nature of the disease "Parangi" show how various they are. Then, we learn from the report before us that "there seems to be very little ground for supposing Parangi to be syphilis or its manifestations," so that the conclusion appears inevitable that in plain English the nature of the malady is not known. Fortunately, however, it is not a fatal disease. Although unsightly, it exerts but slight influence on the general health and longevity of its subjects. Treatment consists in the use of good food, with tonics, mercury, hemidesmus, sarsaparilla, and, in cases attended by rheumatism, iodide of potass. Hospitals have been established in the heart of the island, and medical aid brought as it were to the very doors of the people; yet the results are said to be not satisfactory. Briefly summed up, then, what we learn about the Parangi disease in Ceylon amounts to this: We do not know its nature; the persons affected with it do not die of it; they do not desire medical treatment for it; they only wish to be left alone. It is something for us to have clear information on all these points.

Notes on Current Topics.

The Catgut Ligature.

It is little more than a year ago that Mr. Lister delivered his presidential address to the Clinical Society of London on the catgut ligature. In it he described a method of preparing the catgut by soaking it in a watery solution of carbolic and chromic acids, whereby it was strengthened and in other ways adapted to the purpose of tying arteries in continuity. On Friday last he declared that, after delivering the address referred to, and which he believed to include the final results of his experiments, he was disappointed at discovering that ligatures prepared in the way recommended varied a good deal, the thicker ones becoming speedily infiltrated at the surface in place of being eroded. Further inquiries and careful experiments led him to associate the faults complained of with details of manufacture of the catgut. Following out the line of experiment suggested in this connection, he finally secured a catgut free from the ill qualities which made the chromicised substance of less value. This desirable end is attained by steeping the catgut, first in a solution of chromic acid, 1 per cent., for twelve hours, and subsequently in sulphurous acid, B.P. strength, for the same length of time. The material thus prepared can be stored in the dry state until required for use, thus doing away with the need for keeping in carbolised oil, as must be done in the case of the chromicised gut previously described by Mr. Lister. The new ligature before using is plunged into a watery solution of carbolic acid, which can be kept on the tray containing the instruments; and its inventor claims for it that the infiltration observed in the case of other catgut ligatures does not occur with it, and that it is eminently strong and adapted to the purpose of tying vessels.

Bath Royal United Hospital.

SOME time ago we referred to the affairs of the Royal Bath United Hospital in connection with the dissatisfaction aroused from the want of assistant physicians and surgeons on the staff. A result of the publicity given to the matter was the appointment of a committee to discuss the whole question, and this committee presented its report at a meeting of the subscribers to the hospital a few days ago. An almost unanimous decision was then arrived at to elect three assistant officers in both the medical and surgical departments, the appointments to be for five years, but the holders to be eligible for re-election. A committee of subscribers will be entrusted with the duty of conducting these elections; and the gentlemen chosen will be charged with the care of out-patients principally, but, in the absence of their senior *confrères*, will be expected to do the work of the latter also. This change was certainly demanded, for many reasons, since the full working staff of the hospital prior to the new appointments consisted of three physicians and three surgeons, while the house contains 120 beds, and over 10,000 out-patients per annum apply for assistance.

Jumbo.

PUBLIC interest is notoriously to be excited with the utmost ease in respect to any event which is paraded in a sufficiently judicious manner, but it can hardly be said, nevertheless, that in the case of the elephant "Jumbo" there was any set design to create a widespread excitement on his account. That the question of his removal from his home in the Zoological Gardens has aroused a wonderful amount of affectionate unwillingness to lose him is, however, impossible to doubt; and hence the eagerness with which every detail respecting him is welcomed by his friends. It is right to assume that the officers of the Society were best able to judge of the risk incurred by keeping the monster animal in the Gardens; but notwithstanding, it is difficult to reconcile the statements made by them on the one hand, with, on the other, those made respecting the power of controlling elephants in a "must" condition, by several independent observers who had been familiar with their habits in India. According to these latter, the idea of real danger need not be entertained; but, apparently, such opinions have no weight with the Council of the Zoological Gardens, since we hear of no alteration in the arrangements, according to which "Jumbo" will grace Mr. Barnum's menagerie. Several curious suggestions for controlling the elephant's excitement have been made, and among them one by a medical gentleman, to the effect that bromide of potassium might be found sufficient. The ingenious prescriber does not say in what doses he would recommend the drug to be given; the information might be useful.

Cambridge Local Examinations.

THE Cambridge Local Examinations, by means of which students may pass the preliminary examination required by the General Medical Council, and students proposing to enter the University in October may obtain the certificates which exempt from the previous examination of the University, will be held on Monday, Sept. 4th, in Cambridge and London, and at such other places as the Syndicate may determine. Forms of entry, signed, must be sent in before Aug. 1st. They can be obtained, for Cambridge, from the Rev. G. F. Browne, St. Catherine's College, Cambridge; and for London, from R. St. J. Corbet, Esq., 10 Portman Street, W.

A Disgrace to Kent.

RECENTLY a woman committed suicide by drowning in the Thames, and her body, first seen floating in the river at Cressness, at 10 in the morning, was permitted to remain unrecovered until 5 o'clock in the afternoon, although during this time some hundreds of people were aware of the corpse being in the water, and it was twice left dry. This disgraceful state of things is due to the fact that the West Kent justices abolished the fee of 5s. formerly paid for bringing ashore a dead body, at the time of the unfortunate wrecking of the *Princess Alice* steamer. In the absence of this paltry reward it seems, therefore, that no inhabitant of Cressness deems it worth the trouble of putting forth a boathook in order to reclaim a body from the river; and as the fact must be known to the magistrates, who oppose the payment of two half-crowns per corpse, we are justified in classing them as equally careless of the

claims of the dead. Since West Kent cannot afford to support this drain upon its resources, perhaps some charitable fund may be made available for future payments of the five shillings to persons who may observe floating corpses, and who but for the reward would let them float.

Vivisection and Dogs' Friends.

AN attempt was on Saturday last made by Miss Frances Power Cobbe to depose Mr. Geo. Fleming, President of the Royal College of Veterinary Surgeons, from his seat on the Committee of Management of the Home for Lost and Starving Dogs. The occasion was a meeting of the members and friends of the Home, and the reason assigned for the proceeding was that Mr. Fleming had published an article in demonstration of the benefits conferred on animals themselves by vivisection. We can quite understand the bitterness with which anti-scientific enthusiasts regard the rapid growth of public opinion in favour of vivisection since the attempt has been made to put the real facts of the case before the world by qualified authorities; but none the less it is to be regretted that persons of Miss Cobbe's standing should so foolishly cling to their mistaken views. Of course the amendment proposed by this lady was ignominiously defeated. We trust we may hear no more of such misguided and nonsensical opposition to the spread of truth.

History of Inebriety as a Disease.

UNDER this title a communication appears in the *Detroit Medical Review* from the pen of Dr. Crothers, of Hartford, Conn. He points out that inebriety was recognised as a disease, long before insanity was thought to be other than spiritual madness, as a possession of the devil. This disease was hinted at in an early age of the world, and is by no means a modern idea. On an old papyrus found in one of the tombs of Egypt dating back to a very ancient period was a very significant passage referring to an inebriate who had failed to keep sober. Many of the sculptures of Thebes and Egypt exhibit inebriates in the act of receiving physical treatment from their slaves, such as purgatives, rubbings, or applications to the head and spine. Herodotus, five centuries before the Christian era, wrote "that drunkenness showed that both the body and soul were sick." Diodorus and Plutarch assert "that drink madness is an affection of the body which hath destroyed many kings and noble people." Many of the Greek philosophers recognised the physical character of inebriety, and the hereditary influence or tendencies which were transmitted to the next generation. Laws were enacted forbidding women to use wine, and young boys were restricted. In the first century of the Christian era, St. John Chrysostom urged that inebriety was a disease like dyspepsia, and illustrated his meaning by many quaint reasonings. This was the first clear distinctive recognition of the disease which had been hinted at long before. In the next century Ulpian, the Roman jurist, referred to the irresponsible character of inebriates, and the necessity of treating them as sick men. Many of the early and later writers of Roman civilisation contain references to drunkenness as a bodily disorder, not controllable beyond a certain point, which resulted in veritable mad-

ness. Little reference was made to this theory until the thirteenth century, when one of the Kings of Spain enacted laws fully recognising inebriety as a disease lessening the punishment of crime committed when under the influence of spirits. In the sixteenth century the penal codes of France and many of the German States contained enactments which recognised the disease character of inebriety. All punishment for crime committed during this state varied according to the condition of the prisoner at the time. In 1747 Condillac, a French philosopher, wrote expressing clear views of the disease of inebriety, also that the State should recognise and provide means for its treatment. He asserted that the impulse to drink was like insanity, an affection of the brain which could not be reached by law or religion. Dr. Benjamin Rush, of Philadelphia, in 1790, set forth the same theory, supported by a long train of reasoning. To him belongs the honour of first elaborating this subject and outlining what has been accepted half a century after.

Professor Pasteur's Preventive Inoculations of Charbon.

THE PRUSSIAN Minister of Agriculture, the *Deutsche Med. Woch.* (Feb. 11) states, has appointed an influential scientific committee to superintend and report upon a series of inoculations to be performed by one of Pasteur's assistants. This gentleman then proceeds to Russia for the same purpose, and on his return to Saxon Prussia, where the experiments are to be made, will perform a second series of inoculations. Besides some celebrated veterinary professors, Prof. Virchow is expected to take part in the inquiry; but regret has been expressed that Prof. Koch, the able critic of Pasteur, has not been nominated.

Notification of Infectious Diseases.

AT the recent special meeting of the Lancashire and Cheshire Branch of the British Medical Association, convened to consider this subject, Dr. Carter, of Liverpool, gave an analysis of the working of the Notification Acts in some of the English towns, which takes the bloom off the rose-coloured reports of the success of the system which have been used by notificationists to advance their cause, and which hitherto have passed as gospel because no one had taken the trouble to sift their truth. Dr. Carter said the medical man had always hitherto been regarded as the trusted friend and adviser of those who consulted him. Let it be once felt, however, that to call him in would be necessarily to publish the fact of infectious disease, if it happened to exist, and he would be looked upon with distrust as a sanitary detective, and his services postponed till the last moment. And the skilful direction which he was both able and willing to give to prevent the spread of infection being absent during this period of postponement, disease would spread. In illustration, he quoted from a communication sent by a medical officer of health for a town where such principles were embodied in a local Act, to the effect that children were removed during the night, owing to the fear of a certificate from him. Dr. Carter further quoted from the annual reports of various medical officers of health of towns having these powers, in proof of his contention,

Warrington, during 1880, had 65 notifications of scarlet fever and 14 deaths, or 1 in every 4.6. Bolton had 102 notifications of typhoid fever and 23 deaths, or 1 in every 4.4—a death-rate which was half as high again as that of the London Fever Hospital; the only possible inference from these figures being either that many cases were never notified—*i.e.*, were concealed, and thus the death-rate made to appear high, or else that the administration of the Act proved very fatal to individuals. In Huddersfield, during the same year, the mortality from typhoid fever was exactly double that for the entire kingdom at the date of the latest returns; and complaint was repeatedly made throughout the report of a delay of ten days, and even three weeks, having occurred before the sanitary officer became aware of the cases. Greenock obtained an Act in the same year as Bolton (1877), and great anticipations of its success were formed, and publicly expressed; yet in October, November, and December, 1880, while there were reported to the sanitary officer 86, 266, and 101 cases respectively, there were hunted out by the sanitary officers sufficient additional ones to swell the numbers to 260, 588, and 161—an obvious proof of extensive concealment.

Questions in our Medical Societies.

THE usefulness of our medical societies would be enhanced if, instead of accepting addresses, papers, communications, &c., they would bring up certain subjects for debate, and collect evidence on many of the moot points about disease. Take, for instance, "scarlatina;" there is no more common disease than this modern plague of domestic life, a disease which strikes terror into every household. Yet there is the widest difference of opinion on some very important questions affecting this disease. How long is the period of incubation? Twenty-four hours, or twenty-four days? What is the nature of the poison? Why does milk seem to carry the infection? When is the more dangerous period? Incubation or desquamation? If a child is sent to an hospital, or isolated, how long should it be kept in quarantine, six weeks, eight weeks, or three months? When desquamation is spreading, say 14th day, and the body is free from any seeming disease, may the disease be propagated by the urine, viz, by the renal epithelium? We could mention questions *ad infinitum*. Turning from medical to surgical practice, there are questions for debate without end—practical questions to which practical answers might be given. In all societies this method of arriving at some defined and practical answers to vexed questions should be more generally followed. We commend these suggestions to the presidents of our learned societies.

Salicylate of Soda in the Treatment of Iritis.

DR. CHISHOLM (*Cent. f. Prakt. Hugenheilk*) has given large doses of the above drug in cases of acute episcleritis, even in specific cases where mercury and iodide of potassium had not afforded satisfactory results. He employed at the same time mydriatics. Salicylate of soda was administered every three hours, in doses of 9 to 12 grammes in the twenty-four hours, the dose diminishing as iritis showed signs of improvement.

Dr. Kenny's Case.

DR. LYONS asked the Chief Secretary for Ireland if the Government had come to any decision in reference to Dr. Kenny, a now released suspect, who had been deprived of his appointment as medical officer to the North Dublin Union, and whose case excited much discussion in Committee on Thursday. Mr. Forster replied that if Dr. Kenny were again elected there would be no objection on the part of the Government to the appointment.

Gastrostomy.

THE case recently communicated by Mr. Croly, of the City of Dublin Hospital, in which he endeavoured to prolong life in a case of malignant stricture of the œsophagus, was incorrectly reported in our columns as a case of gastrotomy. It should have been described as Mr. Croly communicated it, as a case of gastrostomy, the term being the proper one for the operation, which has for its object to make an artificial mouth for the introduction of nutriment directly into the stomach, the term gastrostomy being applied to the opening of the stomach for removal of a foreign body.

The Salary of the Coroner for Dublin.

The City Coroner, Dr. Whyte, was appointed five years ago at a salary of £500 a year, and recently the Finance Committee of the Corporation recommended an increase of £50 per annum, which they afterwards for some reason or other rescinded. The Under Secretary for Ireland last week informed the Town Council that as they and the coroner were unable to agree as to the amount of salary to be paid the latter, it would become the duty of the Chief Secretary to determine the amount. The Corporation have referred the matter to the Finance Committee for consideration and report.

M. J. M. CHARCOT (*Comptes Rendus*) recognises in "hypnotism" three distinct stages—the cataleptic state, lethargy, and somnambulism.

At Ramsgate, last week, a dealer named Crow, died of glanders, caused by scratching his hand with a horse's tooth while administering a pill.

At Kingsbridge, Devon, last week, William Elliott, surgeon-dentist, was charged with attempting to murder Miss Polyblank, the daughter of his landlady.

It is proposed to erect a convalescent hospital at Milford, near Stafford, as a memorial to the late "Sister Dora," so well known for her self-sacrificing labours in connection with the Walsall Cottage Hospital.

LADY HARRIET BENTINCK, who gave a donation of £4,000, to purchase new premises for the International Hospital at Naples, has added a new gift of £500 to the former sum.

THE injunction to restrain the Fulham Board of Works from building a small-pox hospital on Wormwood Scrubs

has been withdrawn by the defendants undertaking not to proceed.

SURGEON-GENERAL FASSON, principal medical officer in charge of the Aldershot Division, suddenly expired on Sunday morning whilst partaking of breakfast. He had been suffering many years from heart disease.

WE understand that the funds of the London Fever Hospital are so low, that unless liberal subscriptions are sent to the treasurer, two of its wards will have to be closed.

THE Brighton Town Council have decided to purchase Preston Park from Mr. Benett-Stanford, at the price of £50,000, for the purpose of converting it into a public recreation ground.

AT the banquet given by the Lord Mayor of London on Saturday last to the representatives of "Art, Science, Literature, and Medicine," Sir William Gull, Bart., and Dr. Andrew Clark responded to the toasts drunk in honour of the medical profession.

SIR ERASMUS WILSON, F.R.S., will preside at the Annual Festival Dinner of the Royal Medical Benevolent College on Wednesday, April 19th, at the Langham Hotel. Members of the profession willing to act as stewards are invited to send their names to the Secretary, at the offices of the College, Soho Square, London.

THE mortality last week in the large towns from diseases of the zymotic class, per 1,000 of the population, was—From whooping-cough 4.3 in Brighton, 3.8 in Huddersfield, 2.7 in Wolverhampton, and 2.5 in London; from measles 10.5 in Dublin, 6.9 in Preston, 5.9 in Norwich, 3.4 in Bolton, and 3.3 in Brighton; from scarlet fever, 4.0 in Nottingham, 3.0 in Hull, and 2.4 in Brighton; and from fever, 1.0 in Liverpool, and 0.9 in Oldham. The 45 deaths from diphtheria included 14 in London, 8 in Glasgow, 7 in Portsmouth, 5 in Liverpool, 3 in Leicester, and 2 in Birmingham. Small-pox caused 29 deaths in London and its suburban districts, 2 in Bolton, 2 in Leeds, and one in Manchester.

IN the principal foreign cities the rates of mortality per 1,000 of the various populations were, according to the latest official weekly returns, as follows:—Calcutta 29, Bombay 34, Madras 42; Paris 31; Geneva 30; Brussels 26; Amsterdam 25, Rotterdam 26, The Hague 24; Copenhagen 36; Stockholm 26; Christiania 23; St. Petersburg 49; Berlin 25, Hamburg 31, Dresden 25, Breslau 31, Munich 40; Vienna 32, Prague 37, Budapest 47, Trieste 29; Venice 37; Alexandria 34; New York 34, Brooklyn 25, Philadelphia 25, and Baltimore 27. Rome and Naples again sent no returns; this has been the case for the past three months, and we presume these must now be taken out of the category of "principal cities," as there is an evident intention not to enlighten the profession or the public on this point.

Scotland.

(FROM OUR NORTHERN CORRESPONDENTS.)

THE ELECTION OF PROFESSORS IN THE UNIVERSITY OF EDINBURGH.—It appears that the great objection to one of the candidates for the vacant chair in the University is that he is not "sound," or, in other words, that he has been known to honestly express opinions which in the view of certain pious persons are not strictly orthodox. In a country like Scotland, where more attention is paid to the pious ejaculations of an ignoramus than the honest convictions of a man, and where external professions of piety are more valued than rigid rectitude of conduct, an insinuation of "unsoundness" is social ruin. So strong is this feeling in the country that a professor at another University owes his chair entirely to the fight between "piety" on the one hand and honest conviction on the other; for until the moment of his election he had not turned his attention specially to the subject of his chair. To the misfortune of Edinburgh, strict "soundness" does not appear to go hand in hand with great intellectual attainments.

REGISTRAR-GENERAL'S RETURNS FOR FEBRUARY.—The monthly return of the births, deaths, and marriages registered in the eight principal towns of Scotland, states that during February, 1882, there were registered the births of 3,273 children, of whom 1,700 were males and 1,573 females. Illegitimate births constituted 7·7 per cent. of the whole. In Greenock, 3·6 per cent. of the births were illegitimate; in Perth, 3·8; in Paisley, 5·4; in Leith, 6·5; in Glasgow, 7·4; in Edinburgh, 8·5; in Dundee, 9·6; and in Aberdeen, 11·2 per cent. 618 marriages were registered. This number is 14 above the average for February during the last ten years, allowing for increase of population. The deaths of 2,160 persons were registered, of whom 1,101 were males and 1,059 females. This number is 544 under the average for the month during the last ten years. The mortality was at the annual rate of 18 deaths per 1,000 persons in Dundee and in Aberdeen, 19 in Edinburgh, in Greenock, and in Leith, 24 in Glasgow and Paisley, and 27 in Perth. Of the 2,160 deaths, 850 or 39·4 per cent., were those of children under five years of age. In Leith, 24 per cent. of the persons that died were under five years of age; in Edinburgh, 29; in Paisley, 35; in Dundee, 36; in Aberdeen, 39; in Perth, 43; in Glasgow, 45; and in Greenock, 47 per cent. The miasmatic order of the zymotic (epidemic and contagious) class of diseases proved fatal to 318 persons, constituting 14·7 per cent. of the whole mortality. This rate was exceeded in Glasgow, Leith, and Perth. Whooping-cough was the most fatal epidemic, causing 76 deaths, or 3·5 per cent. of the whole mortality. In Glasgow, 5·1, and in Aberdeen, 5·7 per cent. of the deaths resulted from whooping-cough. Fever caused 50 deaths, of which, 16 were tabulated as typhus, 33 as enteric, and 1 as simple continued fever. 8·2 per cent. of the deaths in Leith were caused by fever. The deaths from inflammatory affections of the respiratory organs (not including consumption, whooping-cough, or croup) amounted to 457, or 21·2 per cent. Those from consumption alone numbered 251, or 11·6 per cent. 80 deaths were attributed to violent causes, of which 3 were suicidal. One death was caused by delirium tremens, and 6 by the direct effects of intemperance.

PROPOSED CHAIR OF PATHOLOGY IN THE UNIVERSITY OF GLASGOW.—Dr. J. A. Campbell, of the Garlands Asylum, Carlisle, intends, at the meeting of the General Council of the

University of Glasgow, to be held on the 26th prox., to move "That a Committee of Council be appointed for the purpose of obtaining the assistance of graduates and others in endowing a Chair of Pathology in the University." We confess that we do not think it the least likely that the bulk of medical graduates will afford any such support, feeling, as most of them do, that medical classes have, in recent years, scandalously increased, merely for the benefit of the lecturer, and that the monopolies of teaching held by the Universities is neither good for the State, the community, nor calculated to advance science. The majority of the profession rather hope that by forthcoming legislation the right to teach shall be distributed in an enlightened manner, and that he who best merits them may win the rewards of teaching any branch of medical science. There is much reason for the reproach of stationariness levelled at the science of medicine, and we feel persuaded that it is mainly due to State instituted monopolies, whereby incompetent men are appointed to professorial chairs solely on account of social or political influence.

SALT A LITTLE.—Specialism must surely pay well in the North, if it be true that a pushing specialist north of the Tweed charges thirty guineas for "four or five consultations." If it be not true, then the story should not be so current in professional circles; and if it be true, too great publicity cannot be given to the matter.

OUTBREAK OF MEASLES IN PORTOBELLO.—An epidemic of measles, which has assumed unusual proportions, has recently broken out in the burgh of Portobello. The disease has principally attacked the children of the working population in the west end of the town, and has spread so rapidly that it has become necessary to close the public schools. It is said that out of between 700 and 800 pupils on the roll more than 300 were absent on account of measles. The cases are fortunately of a very mild type, but more children have been affected than during any previous outbreak. The schools will not probably be re-opened for several days.

ABERDEEN UNIVERSITY.—DEGREE OF LL.D.—At a meeting of the Senatus of Aberdeen University on Saturday the degree of LL.D. was conferred on the following gentlemen:—Mr. Alexander Cruickshank, M.A., Aberdeen; Bey James Grant, M.A., Cairo; Professor W. A. Hunter, University College, London; Professor M'Kendrick, Glasgow; and the Rev. W. R. Smith, Edinburgh.

Literature.

DANGERS TO HEALTH. (a)

THE title of this work, the first edition of which we have already reviewed, although rather too comprehensive, is to a considerable extent borne out by the contents; and few, if any, of the more important sanitary defects unfortunately of such frequent occurrence are left unnoticed. The illustrations, which are numerous, represent truthfully and forcibly many of the dangerous imperfections in sanitary arrangements not uncommon even in the dwelling-houses of the wealthy. The author appears disposed to consider "water sealing" and the liberal employment of syphons as the chief remedy for defective drainage, so far as regards the escape of foul gases from sewers into houses; and no doubt, this remedy is efficacious in many instances. It should be remembered, however, that when sewer gas is abundant, and the water in the syphon is unchanged for any length of time (as occurs, for example, at night), sewage

(a) "Dangers to Health: a Pictorial Guide to Domestic Sanitary Defects." By T. Fridgin Teale, M.A., Surgeon to the General Infirmary at Leeds. London: J. and A. Churchill.

gas is rapidly absorbed at one surface of the water seal and given off at the other, thus permitting foul gas to enter the house. The author does not appear to attach sufficient importance, or draw sufficient attention, to the subject of ventilation, and the free admixture of fresh air, which is one of the great correctives supplied in nature for preventing the evil effects of concentrated gaseous impurities. The doubt which we throw on the efficiency of water sealing is, perhaps, somewhat startling. But we imagine that the power of water to absorb gases is hardly sufficiently considered. One cubic inch of water absorbs two and a half cubic inches of sulphuretted hydrogen; of ammoniacal gases, six hundred cubic inches; of sulphurous acid, forty to fifty cubic inches, &c. Of course, when the water becomes impregnated, even to a small extent, it begins to smell—i.e., gives off gases at the house side, and this must go on all night. This idea, which was brought to our mind by the following quotation made by the author of the book under review, from a paper by Dr. Fergus in the *Edinburgh Medical Journal*, July, 1878:—"A much more important factor in the admission of sewer gas into houses is the diffusion of gases through water." Dr. Fergus detected ammonia in fifteen minutes, sulphurous acid in one hour, sulphuretted hydrogen in three to four hours, chlorine in four hours, &c. For this reason we think that too much reliance should not be placed on water sealing, to the neglect of ventilation. The book is written in homely language, completely devoid of technicalities; and Mr. Teale's remarks can be understood and appreciated by anyone of the most moderate intelligence.

Correspondence.

THE DENTAL DIPLOMA TRADE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me to say that the two quacks registered in the *Dental Register* as licentiates of the Royal College of Surgeons of Ireland had not, as you imagine, been prosecuted previously to their registration by that most excellent Association, the Medical Defence Association, but by the Medical Alliance Association. There are the names of two other quacks, with foreign bogus diplomas, whom the Alliance prosecuted on two different occasions, are also to be found in the above-named register, so that all these defeated quacks were transformed by the Dental Act into legally qualified, not only "dental surgeons," but, according to the ruling last year of the General Medical Council, into legally qualified medical practitioners as well. A very nice Act that Dental Act, especially as construed by the far-seeing members of the Medical Council.

I am, Sir, your obedient servant,
R. H. S. CARPENTER,
Hon. Sec. Med. Alliance Association.

March 8, 1882.

ANALYSES UNDER THE FOOD AND DRUGS' ACT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I think I have reason to complain of the tone and of some of the statements made in an annotation in your issue of March 1st. I hope you will allow me to say that I have nothing whatever to do with putting in force the Sale of Food and Drugs' Act. The inspector appointed under the Act purchases samples, a third of each of which he submits to me with a number affixed, and I certify that I have analysed sample numbered . . . and am of opinion it is genuine, or contains . . . per cent. of foreign ingredients. The certificate is addressed to the inspector, who reports to committee, and takes his instructions from them. I never advise or have any voice in the matter as to what food is purchased, or where it is purchased, or whether proceedings should be taken. I volunteered no evidence gratuitously or otherwise, and was not even present when the verdict was given against the Corporation. When a tradesman is summoned the practice is for my certificate to be put in as evidence against him, and if he wishes to appeal to Somerset House it is open for him to do so on paying a fee of 10s. 6d. There is no evidence that the sample certified by Dr.

Campbell Brown to be genuine was a portion of the coffee sold to the inspector. It was not one of those sealed samples made up by the inspector. Moreover, the magistrates most distinctly stated that the only analysis before the Court, on behalf of the defence, was that from Somerset House.

I certainly do hold the opinion that the microscope is not the only test to be relied on for the detection of chicory in coffee. While I say this, I am sure I should be the last to disparage the use of the microscope in food analysis.

I am, Sir, yours, sincerely,

FRANCIS VACHER.

Birkenhead, March 7th, 1882.

MODIFIED AND NATURAL SMALL-POX.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with very great pleasure the correspondence which appears in the *Medical Press and Circular* for February 8th, between Dr. Andrew Buchanan and Mr. P. A. Taylor, M.P., on this absorbing subject, and, with your permission, would like to add my testimony as bearing out one most important paragraph in Dr. Buchanan's letter of January 11th—viz., "Among the lower ranks the disease very frequently is never discovered. A man feels quite well and takes his food, and is not disturbed by a few pimples on his face. The thing is only discovered when some person gifted with the *tactus eruditus* looks, perhaps, on two pimples on the back of the neck or on the brow, and pronounces them to be genuine variolous pustules." In the year 1877 a small-pox epidemic was prevalent in the City of Dublin. I was then a student, and clinical clerk to physicians of Sir Patrick Dun's Hospital, and during the short period of six months I am fully confident over 200 outdoor patients came to the hospital dispensary, presenting themselves for "a dose of salts" to relieve what they in their ignorance believed was a "heat of the blood" from a disordered stomach, the so-called "heat of the blood" being variolous eruptions in its various stages, and in addition the majority of the students who were re-vaccinated showed the general symptoms, with one or two pimples on the forehead and wrists. With your sanction, I will add my insignificant quota to the many influences now being brought to bear on Mr. Taylor in trying to convince him of the "error of his ways."

I am, yours faithfully,

ROBERT J. BAYLOR.

King Street, Fermoy.

VACCINO-TUBERCLE AND VACCINO-SYPHILIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I shall feel obliged by your permission to say a few words on vaccino-tuberculosis, now under discussion in your journal.

As regards the possibility of either syphilis or tuberculosis being conveyed from one individual or animal to another by vaccination, I think there can be little doubt. During the last two years I have seen among the children attending the out-patient department of the North-West London Hospital three who were attacked after vaccination with a cutaneous eruption of a most suspicious character, and in one, at all events, I think I may with certainty say that the disease was of a syphilitic nature. In all these cases the patients were perfectly healthy before vaccination. In fact, this danger is generally admitted even by strong advocates of compulsory vaccination. Thus, Dr. Martin characterises on this account as abominable the use of any other than the calf lymph, and others identified with this lymph are of the same opinion. What is here possible as regards syphilis, is, I think, also possible as regards tubercle, and that the latter is not brought prominently to our notice is due to the character, seat, and difficulty attending the early recognition of tuberculosis in infantile life.

Dr. Donovan, in your issue of the 1st instant, says, "that vaccination (properly performed) is incapable of conveying either tubercle or syphilis, or any other disease except vaccinia."

The correctness of this statement must be judged according to the signification of the qualifying words, properly performed,

the test of which proper performance can only be discovered by the result of the operation, which is obviously begging the question. That your correspondent in his large experience has never known a case of syphilis or tubercle to follow vaccination only shows the care he has given to his patients, but is besides the question as to the possibility of the propagation of these affections by vaccination. As regards the *impossibility* of the vaccine virus becoming contaminated by other impure matters in the blood, this statement is a mere assertion—has never been proved, and is never likely to be, until at least it can be shown that the respective principles of vaccinia or syphilis are incompatible, and, like oil and water, incapable of commingling. Nevertheless, while believing in the possibility, probability, and, under certain conditions, even in certainty of tuberculosis being transmitted by vaccination, still it is my opinion, at all events in agricultural districts, that with great care in the selection of lymph, the dangers incidental to vaccination from foreign contamination ought to be rendered very slight indeed.

But whether from insuperable difficulties intrinsically connected with the selection of lymph, owing either to irremediable carelessness or other causes, it is certain that the dangers incidental to vaccination are neither infinitesimal or mythical, but actually present, and occasionally repulsive. Therefore, I think if compulsory vaccination is to be maintained, the public are entitled to protection from all risks from whatever cause arising. This protection, and I am now merely speaking of the dangers incidental to vaccination, and not as regards its protective power, can, I think, be given by the universal use of calf lymph. For with proper precautions, not difficult to observe, the chance of communicating disease is reduced to such a minimum that the pedestrian in the streets runs 1,000 times more risk of damage than the recipient of the calf lymph virus. No doubt we have to remember the many bovine diseases that may be communicated to man, and we must bear in mind that there is good reason to believe that at least 5 per cent. of our stable-fed dairy cattle are tubercular, and that the flesh and milk of such animals cannot be taken with impunity, at all events, if they are in an advanced stage of the disease. This, however dangerous it may be to those who use the flesh and milk of such animals—and I am not aware that the discovery has greatly helped the Vegetarian Society—is plainly outside the question of the conveyance of the disease by vaccination, for there is no difficulty in selecting healthy heifers, as those who wish to visit the lymph depôt in the Marylebone Road may see for themselves. Besides, tuberculosis is exceedingly rare in rural districts, as shown by the power of putting on flesh shown by all those animals—a faculty clearly incompatible with any injurious degree of a wasting disease. The dictum of Cohnheim "that what produces tuberculosis is tubercle, and what fails to do so is not," or, as it may be briefly expressed by the phrase, *omnis tuberculosis e tuberculose*, must, in the light of the experiments of Tappinger and Max Schottellina, be taken as not proven. This part of the subject I entered into fully in my book, and also in an article in the *Medical Press*, December 22nd, 1880. And the same verdict, I think, must fall to Dr. Creighton's conclusions, founded solely on post-mortem inspections, without any history to show that the affected were exposed, or had any opportunity of becoming contaminated.

These contradictions do not affect the main question of the inoculability of the tubercular virus, but they lessen the dictum of Cohnheim's that the tubercular matter, *and it alone*, will produce tuberculosis, though it is very likely that the different results obtained may in a great measure be explained by the different animals experimented on. Cohnheim experimented principally on dogs, while Tappinger and Schottellina experimented on rodents—animals very subject to this disease, and which may have been already the subjects of latent tuberculosis.

I am, Sir, yours, &c.,

D. H. CULLIMORE.

54 Welbeck Street, Cavendish Square,
March 9th.

A FLESH WORM.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I wish to lay before you the particulars of a rather strange illness which occurred in my practice lately. On the 17th day of January last I was asked by a respectable farmer

to visit his son, a boy of ten years old. The man stated the boy had been complaining for several weeks previous to this date of a soreness over his body, that he had lost flesh, was dull, and disinclined to move about. He had over the abdomen and breast several dark-coloured, swollen, painful patches, as if bruised, and was pale and weak. Thinking from the child's appearance that he was suffering from scurvy, I gave tonics with a vegetable and generous diet. Cotton with olive oil was applied to the swollen parts. This swelling would remain for some days in one place, and then go away, to appear in another. In several parts of the body some of these swollen patches suppurated and broke, leaving a small opening as if it had been cut out with a punch. One of these small tumours appeared on the back, over the left shoulder-blade on the 29th day of January, and after remaining there for some days, it could be traced up the neck to the back of the head. On the 7th day of February this tumour broke, giving exit to a quantity of pus, and a living white-coloured worm. This worm I did not see, as the child's father threw it on the fire. Up to this time I never thought of parasites causing the illness, but now gave particular directions that if any more of the swollen parts appeared about to break a message was to be sent to me, so as to be certain about the statement, and if possible to procure some of the worms. On the first of this month (March) in this way I procured from a tumour on the child's head a white coloured transparent worm with several rings on its body. For about thirty-six hours before these worms make an opening in the skin they cause much pain. The worm I have is about $\frac{3}{4}$ of an inch long and $\frac{1}{4}$ of an inch thick. I believe this worm made its way to the head from the left arm, as there was a tumour on the left arm which went away, and a track like a cord could be traced with the fingers from the arm up the neck behind the left ear to the head. There is another of these tumours on the head at present. To what species these worm belong, or how generated, I cannot tell. They form a small tumour and come out of the skin in exactly the same way as large grubs that appear on the backs of cattle. Please excuse this, and if possible let me know what entomologist or person would be the most likely to ascertain from what species of insect these grubs or worms were bred, and I will forward the worm to him at once. I am most anxious to have this clearly proved, as the case is a strange one.

I am, yours &c.,

HENRY MURRAY.

Portsalon, Croaghross, Letterkenny,
Co. Donegal, March 6th, 1882.

[If our correspondent will forward the worm to our Irish office, 3 Molesworth Street, we will have it examined, and, if possible, identified.—ED. M. P. & C.]

Novelties.

A NEW APPARATUS FOR WASHING OUT THE STOMACH.

A COMMUNICATION on this subject has recently been addressed to the *Société Médicale des Hôpitaux*, Paris, by Dr. Debove, of the Bicêtre. He says the washing out of the stomach is of such importance that it is now an every-day occurrence in hospitals, and will probably become, in a short time, equally common in general practice. He points out certain conditions which the apparatus employed should fulfil. Two things are requisite, firstly that the apparatus should act as a syphon, and secondly that it should be in the form of a flexible tube.

The stomach-pump is a complicated apparatus, which has its dangers. For instance, the mucous membrane of the stomach may be touched by the tube of the pump, in which case the latter would act as a cupping-glass, and the result, were it an ecchymosis, would be serious. Nothing of this kind can occur if the syphon be employed. When the tube, furnished with a funnel, is raised, liquids may be poured through it into the stomach, when lowered it acts as a syphon, and the same liquids are carried off. The aspiration thus produced is never so strong as to cause a lesion of the mucous membrane, and experience proves that it is sufficient to carry off, completely, all products, alimentary or otherwise, which might derange the gastric digestion. The apparatus

should be made of some soft substance, india-rubber for instance, less to avoid an injury of the œsophagus than of the stomach. A tube for forcing in food may be introduced as far as the cardiac regions, or to a variable depth in the stomach; a tube for washing out the stomach ought, however, to touch the bottom of this organ; even if it did not, there would be no difficulty in introducing liquids, but their evacuation will be incomplete. With a rigid tube there is always danger of a lesion, for it is impossible to know exactly to what depth it should be forced, but, with a flexible tube there should be no inconvenience; if too much be introduced it coils round, and never exercises so great a pressure as to become dangerous.

The conditions already mentioned are fulfilled by Faucher's tube. Its management is based on the fact that any body which arrives in the œsophagus is swallowed by this muscular canal and forced towards the stomach. If, therefore, an india-rubber tube be introduced into the back of the throat and pushed towards the œsophagus it will reach the gastric cavity. I, myself, have frequently employed this tube, always with favourable results, but the introduction has often been found impossible owing to the spasmodic contraction of the pharynx on the introduction of a foreign body. In such cases it should be remarked that the doctor is simply a spectator; it is more difficult for him than for the patient to introduce the tube; the intervention of a strange hand, owing to the apprehension excited, increases the spasmodic contraction of the pharynx. The apparatus should therefore, be rigid to overcome the spasmodic contraction, and non-rigid to pass through the œsophagus and into the stomach. M. Debove believes he has overcome this difficulty in the construction of the instrument made to order by M. Mathieu. It consists of an india-rubber tube sliding freely on a mandrel (to facilitate the sliding it should be rubbed with vaseline, or something of that kind). It is first introduced into the pharynx; behind the larynx this introduction is easy because the instrument is curved, and its rigidity overcomes the spasmodic contraction. Thus the great difficulty is conquered: the mandrel should now be kept immovable, so that the india-rubber tube may glide easily over it and thus pass through the œsophagus into the stomach. The mandrel is then withdrawn, and a second tube, furnished at one end with a screw, at the other with a funnel, is added, in order to make the tube so long as to form an effective syphon, by which the stomach can be emptied with ease.

OLEUM RICINI INSIPIDUM.

Messrs. ALLEN AND HANBURY have recently introduced a preparation termed "Oleum Ricini Insidium." It is absolutely pure castor oil, entirely devoid of smell and disagreeable flavour, and therefore does not cause the nausea and after taste which are characteristic of the ordinary variety. We have had the opportunity of employing this "tasteless" castor oil of Messrs. Allen and Hanbury's in a public hospital on a large scale. Its aperient power is complete, and is fully appreciated by the patients, especially by children, who, finding it quite tasteless, never raise an objection to its administration.

DEATH OF SIR WYVILLE THOMSON, F.R.S., LL.D., D.C.L., &c.

In the death of Sir Wyville Thomson, at the comparatively early age of 52, Scotland has lost one of her foremost naturalists, and science one of her hardest and most brilliant workers. The deceased was a descendant of an old Scottish family which had long resided at Bonyade, Linlithgow. His father was a surgeon in the service of the East India Company. Wyville Thomson was born in 1830,

and was educated at Merchiston Academy, and afterwards at the Edinburgh University. It had been his intention to enter the medical profession, but developing a proficiency in those branches more immediately connected with the natural sciences, he became, at the age of 21, a lecturer on botany in King's College, Aberdeen. A year later he was appointed to the same office in Marischal College. Several papers were published by him at this period on the Polyzoa and Sertularian Zoophytes of Scotland, and other such subjects. In 1853, Mr. Thomson became professor of natural history in Queen's College, Cork; but he had only been there a year when he succeeded to the chair of mineralogy and geology in Queen's College, Belfast. To Professor Thomson's labours Queen's College, Belfast, largely owes an excellent museum of natural history—the zoological collection which he brought together being greatly admired. Professor Thomson was, we believe, one of the first to appreciate the importance of inquiring into the conditions of animal life at the bottom of the ocean, where it was almost universally believed by naturalists that no life existed. He had, as he expressed it, "a profound conviction that the land of promise for the naturalist, the only remaining region where there were endless novelties of extraordinary interest ready to the hand which had the means of gathering them, was the bottom of the sea." Holding strongly these views, he urged Dr. Carpenter to use his influence with the Royal Society to induce the Admiralty to give the use of a vessel for scientific dredging. This resulted in the expeditions of the *Lightning* and *Porcupine* in 1868 and 1869, in both of which he took part; the discoveries then made being subsequently given to the world in a work entitled "The Depths of the Sea." On the resignation of Professor Allman, Professor Thomson was elected regius professor of natural history in the University of Edinburgh. The discoveries made by the two expeditions induced the Royal Society again to take the matter up, and the Government agreed to the fitting out of the now famous *Challenger* Expedition, which, it has been generally allowed, was the longest and most remarkable scientific voyage ever undertaken by any country. Of that expedition, Professor Thomson was appointed the scientific chief, the command of the ship being entrusted to Captain Nares, R.N. The large collections made during the voyage were from time to time sent home to Edinburgh, where the head office of the expedition was subsequently established; and it was only appropriate that as he had gathered them from the previously "unfathomed depths of ocean" in all climes, the direction of the work of describing and reporting upon the specimens should be entrusted by the Treasury to Professor Thomson. The method adopted was to arrange the collections and distribute them to specialists, and up to the present time three large volumes of the official report have been published. The work will require some six-and-twenty volumes of the same size to complete it. As the specimens are returned, a complete series will be sent to the British Museum. For the last two years, however, Professor Thomson, on account of ill-health, has not been able to do much in connection with this important work.

Immediately on his return to this country Professor Thomson's services to the cause of science were acknowledged in various quarters. On the 27th June, 1876, he received the honour of knighthood, and the Royal Society of London awarded him one of its gold medals, and the King of Sweden created him a Knight of the Order of the Polar Star. In addition to numerous memorials on zoological subjects and contributions to the proceedings of the scientific societies with which he was connected, Sir Wyville also wrote a preliminary account of the general results of the *Challenger* Expedition, which was published in two volumes under the titles of the "Voyage of the Challenger" and "The Atlantic."

In the University of Edinburgh Sir Wyville was held in high esteem by his colleagues, and among the students he was exceedingly popular, not less for his unflinching urbanity towards them than for the fluent and lucid manner in which he was wont to treat the subject of his prelections. His style of teaching was calculated not so much to cram his hearers with special information as to arouse in them a desire to find the information for themselves. In private life he was regarded by his friends as possessed of a kindly and hospitable disposition.

He is survived by Lady Thomson and one son, an M.A. of the University of Edinburgh, who is at present engaged in the study of law.

NOTICES TO CORRESPONDENTS.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing 26 strings for holding each volume of the *Medical Press and Circular*, can now be had at either office of this Journal, price 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor.

M. D. EDIN. writes as follows: "Sir,—Three weeks ago I was engaged by a gentleman who called at my house one evening about 8 to attend his wife during her next confinement, which was expected to take place in the middle of April. I booked the case, and called a day or two subsequently to make the acquaintance of my patient, who was a stranger to me. A week later I saw an announcement in the paper that Mrs. — had been prematurely confined of a stillborn son, and since then I have had no communication from either the patient or her husband. I am quite sure I was not sent for during the day or night on which the birth took place, nor at any time since. What should I do now?"

[M. D. Edin. had better send in a claim for the fee he usually receives, and, unless objection is raised to paying it, he need not take any further notice of the affair. Having been regularly engaged to attend the confinement, he is legally entitled to the fee.—ED.]

W. L.—We know of nothing which will replace arsenic in such cases.

MR. JAMES LEE.—Guiteau will be hanged on June 30th next. The plea of insanity was not maintained. We believe Dr. Homan's cases were all antiseptic, though nothing to that effect was stated in the article referred to.

MR. PARRY.—The statement was made on the most unimpeachable authority, and may be accepted as absolutely correct. Whatever blame attaches to the person chiefly concerned will be shared as well by those to whom he is responsible. The effects of the censure cannot now be foreseen.

J. K.—Interference in politics by medical men is, in our opinion, much to be deprecated. In any case no defence can be urged of such conduct as you describe. There is no justification for a physician who uses his influence with patients in favour of a particular candidate; and we fancy a statement of the facts in the proper quarter would be followed by prompt reprobation of the offender.

BASIN.—We cannot recommend anything more suitable for the purpose than "Vaseline." We have, however, found Chrism a most excellent basis; it, like the substance first named, is not affected by long exposure. In point of economy, either possesses great advantages.

COUNTRY SURGEON.—No; we should not advise your performing the operation without first obtaining the opinion of a consultant. In all probability he will entirely agree with you that the excision must be performed, but in a matter involving issues of such gravity and importance you owe it both to yourself and to the patient and his friends to fortify your decision with that of a recognised consulting surgeon. As to the operation itself, we cannot offer to suggest who shall do it. As the friends are anxious that you should, you would probably, provided you are willing to accept the responsibility, act wisely by acceding to their wish on the subject.

STUDENT.—We are uncertain whether the lectures are open to students free; they are to members of the profession on presentation of address-card; you will probably not be refused admission.

DR. H. G.—If you will kindly send your MS. we shall be better able to judge of its suitability.

DR. GOYDER is thanked for the "Report of Discussion on Puerperal Fever" at the Bradford Medico-Chirurgical Society, of which early proofs shall be sent him.

A THIRD YEAR'S MAN cannot do better than get and master Harris and Power's little "Manual for the Physiological Laboratory;" we know of no similar work which imparts knowledge so practically, and withal so succinctly.

T. E. C.—We are not cognisant of the process, but will make inquiries and let you know in our next. A pharmaceutical journal would have been the proper medium to which to address the query.

MR. G. S. G.—With all due deference to the opinions of your friends, we think you have been badly advised; there is nothing in which the enthusiasm of a few admirers is so likely to lead to disastrous results as in literature. "Oh, that mine enemy would write a book!"

MR. LAWSON TAIT'S paper will, we hope, appear in our next.

DR. S. G.—We will look into the subject before committing ourselves to an opinion.

NOTICE has been given that an examination of candidates for eight appointments as Surgeon in Her Majesty's Indian Medical Service will be held in London in August, 1882.

THE SOCIETIES, COLLEGE LECTURES, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—This day (Wednesday), at 4 p.m., Prof. W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Edentata."

BROMPTON CONSUMPTION HOSPITAL.—This day, at 4 o'clock, Dr. C. Theodore Williams on "The Treatment of the Temperature of Phthisis."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—This day, at 5 o'clock, Croonian Lectures: Sir Joseph Fayrer, "On Climate and Fevers in India."

ROYAL INSTITUTION.—Thursday, March 16th, at 3 p.m., Prof. Tyndall, "On Resemblances of Sound, Light, and Heat."

HARVEIAN SOCIETY.—Thursday, March 16th, at 8.30 o'clock, Dr. Fitzpatrick, "On a Case of Puerperal Septicæmia."—Mr. W. B. Owen, "On a Retrospect of Fifty Years' Professional Experience."

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Friday, March 17th, at 4 p.m., Prof. W. H. Flower, "On the Anatomy, Physiology, and Zoology of the Edentata."

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Friday, March 17th, at 5 p.m., Croonian Lectures: Sir Joseph Fayrer, "On Climate and Fevers of India."

ROYAL INSTITUTION.—Friday, March 17th, at 8 p.m., Captain Abney, "On Infra-Red Rays of the Spectrum."

ROYAL INSTITUTION.—Saturday, March 18th, at 3 p.m., Prof. H. G. Seeley, "On Volcanoes."

Vacancies.

British Honduras.—Medical Officer for the Corozal District. Government salary, £150, with extra fees. Free passage to Colony. Applications to the Secretary, Colonial Office, London, E.W. (See Advt.)

Epsom Union, Surrey.—Medical Officer. Salary £50, with the usual extra fees. Application to the Clerk of the Guardians by March 21st.

Gairloch, Ross-shire.—Parochial Medical Officer. Salary, £100, with house. Applications to the Chairman, O. H. Mackenzie, Inverewe, Poolwee, N.B.

Hartlepool Union.—Medical Officer for the District. Salary, £50. Also Medical Officer for the Workhouse. Salary, £65. Applications to the Clerk of the Union by May 17th.

Kent County Lunatic Asylum, Chatham.—Second Assistant Medical Officer. Salary £120, with board. Applications to the Clerk of the Committee before March 21st.

Kent and Canterbury Hospital.—House Surgeon. Salary commencing at £80, with board. Applications to the Board of Management by March 30th.

London Hospital.—Assistant Demonstrator of Anatomy in the College. Salary, £90. Daily attendance for four hours during five days each week. Applications to the Warden by March 16th.

North Wales County Lunatic Asylum, Denbigh.—Medical Superintendent. Salary £450, with certain allowances. A knowledge of Welsh desirable. Applications to the Chairman of Committee by March 29th.

Nottingham Dispensary.—Resident Surgeon. Salary, £200, with extra. Applications to the Secretary on or before March 25th.

Taunton Union.—Medical Officer for the Church Stanton District. Salary, £52, with the usual extra fees. Applications to the Clerk at the Town Hall by March 20th.

Appointments.

BROCKNELL, W. H., M.D. St. And., M.R.C.S., Medical Officer to the Beaconsfield District of the Amersham Union.

DAVIES, W., M.B.C.S., Medical Officer to the Llandilo, Talley, and Llanwaele Districts of the Llandilo Union.

GLAISTER, J., M.B., C.M. Aber., Medical Officer to the Rothwell District of the Hunslet Union.

HUTTON, H. E., M.A., M.B. Camb., Physician to the General Hospital for Children, Pendlebury.

KNOTT, W., M.B., C.M., Medical Officer to the Fifth District of the Middlesbrough Union.

LIMONT, J., M.A., B.Sc., M.B., C.M., M.R.C.S., Senior House Surgeon to the Newcastle Infirmary.

LOFTHOUSE, A., M.R.C.S., House Surgeon to the West Herts Infirmary, Hemel Hempstead.

POPHAM, S. L., B.A., M.D. (T.C.D.), Medical Superintendent to the Craiglockhart Hydropathic Establishment.

STAMFORD, W., L.R.C.S. Lond., M.R.C.S., Medical Officer of Health for Tunbridge Wells.

STREET, A. F., M.A., M.B. Camb., M.R.C.S., Junior Resident Medical Officer at the Radcliffe Infirmary, Oxford.

Births.

BLACKETT.—March 5, at Wangford, Suffolk, the wife of Edward B. Blackett, M.D., of a son.

NEDHAM.—March 9, at Westbury Gardens, Clapham Park, the wife of Joseph Needham, M.D., M.R.C.P., of a daughter.

TREVES.—March 10, at 18 Gordon Square, London, the wife of Fred. Treves, F.R.C.S., of a daughter.

Marriages.

MEDLICOTT—BANKS.—March 9, at St. John's, East Dulwich, Surrey. Richard, youngest son of the late K. J. Medlicott, J.P., of Dismurry, co. Kildare, to Louise Mary, second daughter of the late A. J. H. Banks, M.D.

Deaths.

BURROWS.—March 4, at Cavendish Square, W., Minor, the beloved wife of Sir George Burrows, Bart., M.D., F.R.S.

EDGEWORTH.—March 8, at Silchester, Longford, George Thos. Henry Edgeworth, F.R.C.S.I., Surgeon to the Longford County Infirmary, in his 68th year.

GREEN.—March 7, in Dublin, Charles F. Green, M.D., deeply regretted. O'KEEFE.—March 5, at Mountkeefe, co. Cork, Charles O'Keefe, L.R.C.S.I., after a protracted illness.

The Medical Press & Circular.

CLINICAL LECTURES ON SYMPTOMS.

Delivered in the Wards of the Hospital.

By FREDERICK T. ROBERTS, M.D., B.Sc., F.R.C.P.,

Professor of Materia Medica and Therapeutics at University College; Physician and Professor of Clinical Medicine at University College Hospital; Physician to the Brompton Consumption Hospital, &c.

LECTURE X.—SYMPTOMS CONNECTED WITH THE

HEART.—Continued.

(4) SYMPTOMS connected with the *respiratory system* may next be considered in their relation to cardiac affections, and they are present in a large proportion of cases in some degree, being not uncommonly of great consequence, and conspicuously prominent.

a. Disorders affecting *breathing* deserve our first attention, as they are of very frequent occurrence, both in connection with functional complaints and organic diseases of the heart. In every individual case it is important to recognise the nature of the disorder; and also the cause or causes upon which it depends.

The various derangements to which respiration is liable will be discussed in detail when we come to deal with the symptoms belonging to the respiratory organs. In the meantime it will suffice to indicate, without describing at any length, those which are met with in cardiac affections in different cases, either separately, or more commonly in various combinations, including the grave disturbances of breathing which attend suddenly or rapidly fatal lesions connected with the heart, angina pectoris, and allied conditions. They may be arranged thus:—

(i.) *Shortness of breath.*—This is very often present, but varies much in degree, being in some instances only noticed when the patient exerts himself unduly, or walks hurriedly up an incline or up-stairs; in others the

slightest movement or effort causing marked disturbance of the breathing.

(ii.) Actual *dyspnoea*, the patient feeling various degrees of discomfort; and the respiration being more or less hurried, excessive, or laboured at all times, though liable to exacerbations.

(iii.) *Orthopnoea*, the patient being quite unable to lie down, on account of the difficulty of breathing experienced in that posture, and having to be propped up in bed, or even to remain constantly in a heart-chair. This form of respiratory disorder is very troublesome in some advanced cases of cardiac disease. It may, moreover, be present when the breathing is quite undisturbed, so long as the patient is placed in a suitable position.

(iv.) *Paroxysmal dyspnoea.*—The respiration may become temporarily disordered in a marked degree in connection with severe derangement of the action of the heart. The most important deviation, however, to be mentioned here, is that which has been specially termed "cardiac asthma." The paroxysms are of different degrees of severity, and may be very grave, depending or not upon some obvious cause, such as undue exertion, or over-feeding. The breathing becomes excessive; increased in frequency, though not, as a rule, to a great extent; of a panting or gasping, and noisy character; while the air passes in and out freely and without difficulty, so that expiration is not obviously prolonged, and no rhonchi are produced. The patient suffers more or less during the paroxysms, which last a variable time, and this may be evident in his appearance. Persons suffering from cardiac disease may be subject to ordinary spasmodic asthma, associated with pulmonary conditions, but these are independent of the heart.

(v.) *Peculiar disorders.*—Cheyne-Stokes' respiration is met with in exceptional instances of cardiac disease. I have already alluded to an involuntary tendency to sigh, or to draw in a full breath.

We must now consider how disorders of breathing may be originated in connection with cardiac complaints, and I would impress upon you that it is often of essential consequence in a particular case to determine what

causes are actually at work, in order that appropriate treatment may be adopted.

(i.) The breathing may be disturbed merely by *abnormal action of the heart*, which deranges the pulmonary circulation, either causing a condition of active hyperæmia, or rendering the flow of blood through the lungs feeble and imperfect, or unequal. This is a common cause of temporary disorder, and accounts for many cases of shortness of breath. Indeed, this is a physiological effect of undue exertion in any person, and the influence of this cause in morbid cardiac conditions can be readily understood. The way in which the heart acts often aggravates dyspnoea from other causes.

(ii.) In a certain class of cases there is persistent *pulmonary congestion*, in consequence of some impediment to the circulation through the left cavities of the heart, and this materially affects the breathing. As a result of this congestion, œdema of the lungs, or even hæmorrhage into their substance may arise, and the respiration is thus further disturbed. With regard to pulmonary apoplexy, it may also be noticed here that this condition may follow the lodgment in a branch of the pulmonary artery of a portion of clot detached from the right side of the heart. It is not uncommonly observed that in cases of this kind, when in course of time the right side of the heart becomes enlarged, the lungs are relieved, and the breathing is thus rendered easier, while, at the same time, symptoms indicative of general venous congestion supervene.

(iii.) Further, it must be remembered that in addition to what has been just mentioned, there may be more definite morbid conditions affecting the *respiratory organs*, and thus the breathing may be influenced in various ways and degrees. These lesions are either temporary or permanent; and secondary to the cardiac disease, or quite independent of it. In some instances a state of more or less congestion of the bronchial mucous membrane is kept up constantly, and catarrh or bronchitis is thus readily set up by slight causes, or congestion becomes temporarily increased. Again, hydrothorax is a condition that may supervene as a consequence of cardiac disease, and this tends to induce dyspnoea, or to aggravate it. The effects of cardiac disease upon the circulation through the lungs become in time of a permanent character, and are attended with organic changes implicating the lung-tissue and the vessels, which may materially increase the disorder of breathing. Moreover, it must not be forgotten that cardiac mischief is not unfrequently secondary to disease of the lungs, and both may then contribute to the respiratory disturbance. For instance, emphysema causes enlargement of the right side of the heart; the changes which take place in certain chronic cases of phthisis may involve the pericardium and heart, causing adhesions and displacement, and so affecting the action of this organ as to add materially to dyspnoea; while, lastly, sometimes independent cardiac and pulmonary diseases are present in the same case, such as phthisis with mitral disease and its consequences.

(iv.) The condition of the *blood* must also always be taken into account in estimating the causes of disordered respiration in any cardiac case. Anæmia adds very materially to shortness of breath, and may be its sole cause, even when there is actual disease of the heart. Undue venosity of the blood may likewise have some influence. The clotting of blood within the cavities of the heart may produce grave dyspnoea, or aggravate this symptom; and clotting in the pulmonary artery is supposed to be a cause of sudden death, or the passage into this vessel of a clot from the right ventricle.

(v.) I may just notice that occasionally some *other condition*, with which cardiac disease is associated, is the real cause of a disorder of respiration which happens to be present. For instance, this may be due to a thoracic aneurism; or possibly uræmic dyspnoea occurs, the result of renal disease.

(vi.) The influence of the *nervous system* must also not

be forgotten. It certainly may aggravate dyspnoea by disturbing the action of the heart, when this organ is diseased, as well as in functional cases. There may also be mere nervous dyspnoea in both classes of cases.

b. *Cough* is a symptom which may result from cardiac affections, either directly or indirectly. Thus, it may be due to compression or direct irritation of the lungs or air tubes, in connection with pericardial effusion, or a much enlarged heart; or it may be of nervous or reflex origin. Under these circumstances it is usually a frequent, short, and purposeless or ineffectual cough. As a consequence of pulmonary congestion and catarrh this symptom is likely to become more prominent; and still more so when actual bronchitis or other complications supervene, these being attended with expectoration of different kinds.

c. *Hæmoptysis* deserves separate notice as a symptom in some cases of heart disease. The hæmorrhage may be the consequence of mere excessive congestion; disease of the pulmonary vessels; or embolism or thrombosis. The quantity of blood discharged varies much; and it is not uncommonly of a very dark colour, and may be almost black. The occurrence of hæmoptysis is in some instances of cardiac disease distinctly beneficial, and it should not be checked too rapidly, as it may relieve the circulation through the lungs considerably, and thus improve the breathing, without being in such amount as to injure the patient.

(5.) The group of symptoms to which I would now call your attention are those associated with the *nervous system*. To some important phenomena belonging to this group I have already referred, when speaking of sudden attacks in relation to the heart, and of subjective sensations on the part of the patient, and I need not repeat these here. Moreover, nervous disturbance not unfrequently aggravates other symptoms in cardiac affections, and is directly accountable for many cases of functional disorder. There are, however, other phenomena to which I would briefly direct your notice, as they are in not a few instances of much consequence.

a. The *mental condition* is worthy of attention in connection with affections of the heart. In the first place the knowledge or suspicion of the existence of cardiac disease makes many patients very anxious and frightened, or positively miserable and wretched, always dreading sudden death, and this may in itself be a serious matter, while it tends to increase other symptoms considerably. I would mention, by the way, that this fact ought to be constantly and prominently borne in mind in making a diagnosis, or giving an opinion as to prognosis in real or supposed cardiac cases. It is difficult enough to get many persons to believe that they have not heart disease when such is really and undoubtedly the case; but let them once be told by a medical man that their "heart is affected," and it becomes almost impossible to eradicate the notion from their minds. And even when there is actual disease, it is necessary to be very cautious as to what is said to patients themselves, especially if they are at all inclined to be nervous. Even functional disorders are often attended with much mental quietude or distress.

In those forms of cardiac disease which lead to general venous congestion and defective blood-aeration, in which the brain must suffer along with other organs, the intellectual faculties are liable to be impaired more or less, as evidenced by indisposition or inaptitude for mental occupation or effort, confusion of thought and intellectual dulness, incapacity for business, impairment of memory, and other signs of this condition. The disposition, temper, and character of the patient may also be changed, as evidenced by irritability or fretfulness, fits of anger, lowness of spirits, melancholy, deficient firmness of purpose, and a want of mental stability. These alterations are particularly noticed in those who have been previously engaged in pursuits involving active exercise of the mental faculties.

b. *Sleep* is frequently influenced in some way or

other in connection with cardiac complaints, and very opposite disorders may be combined in the same case. Inability to sleep is a symptom which proves very troublesome in many instances, and particularly towards the fatal close of certain cases. This is a prominent phenomenon in some forms of functional disorder of the heart, and no doubt aggravates this considerably, or may even produce it. The patient may feel little or no disposition to sleep, but usually he longs for it, and is actually drowsy; but no sooner does he drop off into slumber than he wakes up with a start or in a fright, with uncomfortable or distressing sensations about the heart, or with a feeling of suffocation. Or he may have short and uneasy dozes, with disturbing dreams, and jerkings or twitchings of the limbs. This disorder of sleep may be materially influenced by posture, and is often greatly relieved by placing the patient in a heart-chair. In contrast to what has just been described, patients suffering from some forms of cardiac disease are always drowsy and somnolent, and sleep heavily a great part of their time. This is especially noticed in cases of cyanosis. Under all circumstances there are likely to be unpleasant and disturbing dreams.

c. Patients suffering from cardiac disease sometimes experience *abnormal sensations* in their limbs in various parts, temporarily or permanently, such as tingling, numbness, &c.; as well as *motor disorders*, of the nature of jerkings, muscular twitchings, or slight paresis. These probably depend on changes in the vascular supply to the spinal cord.

d. Not only may apoplectic attacks occur in connection with heart diseases, but the fatal termination is, in some instances, preceded by increasing somnolence and stupor, culminating in more or less deep *coma*. This condition may be partly due to the renal changes which are induced by certain cardiac affections.

(6.) I have already noticed the temporary disorders of *sight* and *hearing* which may be associated with heart complaints. It will suffice to mention further that the special organs which are concerned with these sensations are, in some forms of disease, liable to present definite organic changes in course of time, and thus they become permanently affected in various ways; and in the case of the eye these changes become visible with the ophthalmoscope.

(To be continued.)

A RESEARCH INTO THE VALUE OF THE DETAILS OF LISTER'S METHOD IN ABDOMINAL SURGERY. (a)

By LAWSON TAIT, F.R.C.S.,

Surgeon to the Birmingham and Midland Hospital for Women; Consulting Surgeon to the West Bromwich Hospital, &c.

I AM reminded that nearly sixteen years ago, just after I had received my first licence to practise, I visited this famous city, favoured by introductions from him who stood then at the head of my department of professional practice, and that he and nearly all those to whom I bore his letters have gone over to the majority.

I am also reminded that the most famous of all the many virtues of this fair island was shown in my own case, in a way which has left a memory of my first visit to Ireland, never to be forgotten; that here I made friends who have ever been kind to me, whom I have often wished to re-visit; that in this Society I received the first surgical distinction I had conferred on me, one I have ever since valued; and last, but certainly not least, I received in this city my first consultation fee.

It is with something far greater, therefore, than pleasure that I find myself to-night addressing one of

the most distinguished societies in the Kingdom, and that to which I was first admitted.

I read with a keen interest the account of a discussion which took place here a little more than a year ago, upon the theory and practice of the so-called antiseptic system of Professor Lister; and I was so struck by some of the arguments used and the illustrations given, that I asked if I might raise the discussion again. Your secretary was good enough to comply with my request, and your council kindly fixed a time convenient for me. I do not know that I have very much that is new to tell you, and perhaps I may utterly fail in convincing you of the correctness of the conclusions I have come to; but I know that Irishmen always deal kindly with a weakling, and are even courteous to a guest.

In a paper which was read before the Royal Medical and Chirurgical Society of London just two years ago, I criticised the doctrines of Mr. Lister from the results obtained in my practice in abdominal surgery; and some of the speakers in your debate did me the honour to quote some of my conclusions, and this it was that emboldened me to re-introduce this important subject before the Surgical Society of Ireland.

Before coming to the details of my research, perhaps I may be permitted to explain certain general principles which are essential to my argument.

The first is, that in the discussion of such a question it is advisable to avoid as much as possible mere empirical statements, and to reduce as much as is practicable all our arguments to something like the tests inflicted by the ordinary canons of evidence. This is no easy matter in our professional details, for it is the exception rather than the rule that we can do more than say that we think a certain proposition to be true. The results of our individual experiences vary so much in extent and in conditions that in almost all our arguments we are driven to the votes of authority. Therefore, when we can proceed upon a purely inductive method the conclusion will probably prove a strong one.

My second proposition is not so secure, but still I attach much importance to it; and it is that the narrower the area over which an experiment is tried, the fewer the elements of disturbance in its conditions and the greater similarity in the conditions of detail, the surer will be the conclusion. Thus my own practice is almost entirely limited to abdominal surgery; and, therefore, an experiment based upon the application of a particular theory to surgical practice will meet with a trial more free from disturbing elements than if I recorded my experience of a mixed practice of amputations, lithotomies, ovariectomies, &c. The reason of this seems to me clear, in that one ovariectomy is of closer value to another ovariectomy than either can be to an amputation, or a lithotomy; and that a series consisting purely of repetitions are better for this purpose than a mixture.

This proposition seems to me self-evident, but if it is not admitted much that I say must fall to the ground. But, mark, I do not mean to assume that a principle which is found absolutely true for the performance of an ovariectomy must necessarily be as true for an amputation. But the proof that it is not true must be shown clearly; and no statement to that effect must be merely asserted, because so many general principles are found to be absolutely true in all such cases.

My third proposition is an empirical one, and open to controversy; but it has received such general acceptance that I must press for its acceptance. It is to be given as a group of conclusions, the first of which is that in the peritoneum we have a cavity peculiarly liable to what we call septic influences. We all know what we mean by these two words, though they defy explicit definition; and the great fatality attending all abdominal operations until quite lately was universally

(a) Read before the Surgical Society of Ireland.

set down to these "septic influences." I have heard it asserted lately that this is not so, and that really the peritoneum seems to be the only part of the body over which septic poisons possess no influence at all. This astounding statement arises out of the thoughtlessness of some of Mr. Lister's too enthusiastic disciples, who, finding that my experience shows that in abdominal surgery we do better without Mr. Lister's details than with them, turn round and utter this extraordinary and revolutionary contradiction. Yet it is the uniform practice of every surgeon about to perform ovariectomy to remove his patient from all possible and recognised sources of septic poisons. This is more rigidly carried out in this particular line of practice than in any other, so that the performance of ovariectomies in general hospitals has been very widely condemned, and its results have never been good. I assume, then, that the field of abdominal surgery affords an especially favourable opportunity for the trial of a system which is based on antiseptic theories; and on this assumption I made an experimental research on Mr. Lister's methods, the details of which I propose to discuss.

Let me first of all say that the theory of putrefaction upon which Mr. Lister bases his practice I regard as having been long ago proved. No known putrefaction can occur save in matter which is dead, and only by means of the admission to it of resting or swarm spores of some of the low forms of life, such as bacteria, bacilli, &c. The only point between Mr. Lister and myself is that Mr. Lister assumes for living tissue the same series of phenomena as he finds in dead infusions, and this I deny altogether. Neither Mr. Lister, nor any of his numerous followers, have ever tackled this important point, and the one experiment upon which Mr. Lister hangs so much, in fact that single argument of his, which has proved such a crux to everyone, rests on this point.

He has told us over and over again, and there is abundant evidence of the correctness of his assertion, that if a deep wound is filled with blood clot, and is dealt with completely by the antiseptic method, that it will become organised and will ultimately form part of the tissue in which it is placed. Everyone knows that without the application of Mr. Lister's details blood clot will putrefy, break down, and disappear. There can be no doubt whatever that here Mr. Lister has established a point of immense importance practically, which is, however, limited to this, that artificially we can make a blood clot do on the external surface of the body what it nearly always does when sealed up in the tissues or in a cavity. Hundreds and thousands of blood clots are organised in the body when covered up, and we think nothing of it. How is it that they do not become so organised on the external surface when ordinary atmospheric air is admitted to them? The answer admits of no dispute, the putrefactive germs breed in them, destroy them, and break them down by putrefaction. You may say, then, that I concede Mr. Lister's arguments, but my answer is that I am not yet done. I have to satisfy myself that a blood clot is dead, or that it is not dead before I go further, at least this was my former opinion. It is probable that the large clots found in the peritoneum, in cases of hæmatocele, do not die, otherwise we should not expect to see many cases of recovery, whereas death is the exception and not the rule, save when it occurs immediately from the hæmorrhage itself. Subcutaneous ecchymoses do not die, and enormous clots are seen to organise and disappear in the scrotum and vulva as long as the skin protects them entirely. The unbroken tissue in fact protects them from the killing influences of the germs. It might be assumed, in fact, that a blood clot is really not dead, but that it is only in a condition in which vitality is so feeble that it is very easily destroyed, and the amount of vitality is not such as to enable it to resist the attacks of bacterian germs, which speedily

kill it. This is perfectly in harmony with Mr. Lister's own views, for amongst the many changes of platform to be found in the history of his theory and practice, is the frequent admission that living tissues have a varying power of resistance of the attacks of germs. We may assume that coagulated blood, maintained at its normal temperature, has the most feeble kind of resistance, and speedily falls a victim.

I further assume as proved that Mr. Lister's details, when carried out, amply suffice for the destruction of germs, and that you may keep a blood clot indefinitely in a solution or under a spray of carbolic acid. If, therefore, you keep a blood clot, not yet dead, at a normal temperature, and fully protected by the details of Mr. Lister's method from the attacks of bacterian germs, you may give it time to become so fully organised as to acquire a power of resisting those germs equal to that possessed by ordinary tissue.

I admitted all this long ago, and I have often confessed that the story of the antiseptic blood clot was a great crux. But the mystery has been fully solved in a most unexpected direction by Dr. D. J. Hamilton, of Edinburgh, in his remarkable papers on "Sponge-grafting." There we find this unexpected display, that a piece of sponge will do quite as well as a blood-clot, and that the antiseptic details are altogether needless. The sponge is dead enough, beyond doubt, and no carbolic acid or other agent is in the least needed to enable it to become organised, or at least to enable it to be the basis of new structure, for perhaps that is the better way to state the case, and it is clearly also the truer way to speak of the blood clot.

Nothing more amazing, nothing more gratifying to the practical surgeon has been produced in this century than the results of Dr. Hamilton's experiments. That a piece of sponge laid on a wound should become part and parcel of the patient's body is almost incredible, yet it is true, and it seems to me completely to explain the mystery of Mr. Lister's blood-clot.

From Dr. Hamilton's conclusions I see that it is not necessary to adopt the assumption I formerly advanced that the blood-clot was really not altogether dead, for he starts with the belief "that blood-clot or fibrinous lymph plays merely a mechanical and passive part in any situation where it becomes replaced by a fibrous cicatrix, and that this vascularisation is not owing to new formation of blood-vessels, but rather to a displacement and pushing inwards of the blood-vessels of surrounding tissues." Being convinced that the blood-clot was just so much dead matter in a tissue, it occurred to him to employ some dead porous animal tissue instead, and for this purpose he selected sponge, and he has proved his case. His cases showed "that even where a wound continues in a putrescent condition organisation will still go on. In the case of the blood-clot putrefaction tends to destroy it; in that of the sponge, its texture being more resistant, it does not seem to make much difference." In fact, with the blood-clot Lister's details only save the non-resistant matrix from destructive putrefaction till the blood-vessels permeate and remove it, just as they ultimately do the sponge, and Dr. Hamilton's experiments utterly destroy the last surviving argument of Mr. Lister. He compares the "sponge and the blood clot, and says of the latter that it is an excessively porous substance. It is more finely porous than the finest sponge. The fibrin forms a network containing only a few blood corpuscles, while the serum is squeezed out of, or drains away from, the interstices. It is, therefore, a tissue which, if its assumed vital properties be laid aside, is extremely like a sponge in its structure, each being composed of a delicate framework with large and small meshes." He speaks in the same way of fibrinous lymph, and his marvellous experiments explain our facts and destroy the last support of Mr. Lister's theories.

I have, therefore, got so far as to have formulized my views to the effect that, whilst accepting the germ

theory of putrefaction in its entirety, I entirely repudiate Mr. Lister's application of it to surgery. Upon it he bases a certain line of practice, more particularly a method of performing operations, which has received such a wide acceptance, which is spoken of in terms of such enthusiasm by men upon whose statements I can place the utmost reliance, that I am almost tempted sometimes to discredit the evidence of my senses, or to come to the conclusion that the tissues of a patient with a disease requiring a pelvic or abdominal operation act in a manner wholly different from those of patients under all other circumstances.

Putting theory and private conviction aside, and influenced solely by a verdict which seemed almost unanimous, and by the surgical conscience which obliges us all to do everything we can and to use everything we know for the welfare of our patients, I gave Mr. Lister's method a trial, which extended over a series of abdominal sections. This was composed of nearly a hundred operations, sixty of which were for the removal of ovarian tumours, and the detailed results of most of them and many others are given in the paper I have already alluded to. The conclusions of the figures, which were not, and so far have not been challenged, were in every way against Mr. Lister's practice; and the influence which has been exercised by this paper has been considerable in modifying the views of a large number of competent authorities upon this important subject.

I announced in that paper that, having come to the conclusion that Mr. Lister's system, when completely used, was prejudicial to my patients, not only in the question of mortality, but in the speed and evenness with which they recovered, I should further inquire into the influence of the method.

For this purpose I divided its details into two groups, those which were essential to the performance of the operation and those involved in the after-treatment of the cases. The latter included Mr. Lister's special forms of dressing, such as protective gauze impregnated with carbolic acid, &c., &c., and these I promptly and at once discontinued, because I had proved in my paper that the patients did better without them. I adopted the absorbent cotton-wool, that is, cotton deprived of its intrinsic oil, and entirely without any so-called disinfectant, and this material I have used ever since. With this dressing I have treated more than two hundred cases of abdominal section, and these have been open to the inspection of many visitors of distinction and numerous professional friends. The verdict is unanimous that no better results could be obtained than are to be seen with my dry dressings. The patients recover smoothly, without any exacerbations of pulse or temperature curves, and primary union is the uniform result.

I had to deal, after that point, with the details of Mr. Lister's system, which are supposed to protect the patients from the influences of omnipresent germs at the time of the operation, and with these it was necessary to make my experiment with very great care in the interests of the patients.

For the sake of convenience I may place these details in three groups:—

1. The use of the spray, which I looked upon as by far the most important, since it covered the whole time of the operation, was absolutely consistent with the theory of the system, and seemed to me, from that point of view, of infinitely greater importance than all the other details put together.

2. The preparation of sponges, ligatures, instruments, &c., previous to the operation.

3. Details of occurrence during the operation, such as washing out the peritoneal cavity, &c.

As carbolic acid is the substance to which Mr. Lister has consistently adhered throughout the whole of his work, and as it is that of almost universal acceptance, my remarks are to be taken as applying solely to it. I

found, previous to this research, that the substance thymol, introduced by Mr. Spencer Wells, was too dangerous to be used, and the results of my research have seemed to me too conclusive to have any need for further experiment.

In order to secure the complete performance of my research I went to very great trouble about the apparatus, especially about the spray producer. I had a very large one constructed, which would produce a continuous jet of spray six feet long, and having a base of nearly four feet in diameter, and this could be continuously maintained for about three hours. The spray used at first was from a solution of one in twenty, then one in thirty, then one in fifty, then one in eighty, then one in a hundred. I then tried one in a thousand, and after that I went on with a spray consisting of nothing but steam and common tap water, and my patients recovered as satisfactorily without the carbolic spray as with it; in fact, I may say that they recovered better without the carbolic acid, for whilst using that substance in a strong spray, I had several indications of carbolic poisoning, and I very nearly lost one case. This was in the instance of a child upon whom I operated for pelvic abscess under a spray of one in thirty. Within a few hours after the operation her urine became quite black from indican, and loaded with albumen. She became unconscious, and finally had severe convulsions. Within forty-eight hours all these symptoms passed off, and she made a perfect recovery.

At the beginning of my research I had all my instruments completely covered in baths filled with a solution of carbolic acid—one in twenty, my sponges carefully cleansed and similarly covered, my ligatures scalded and soaked in the same solution for many hours before the operation, my hands and arms and those of my assistant carefully washed and rubbed over with the solution, and every preliminary detail most carefully carried out.

Then, as with the spray, I slowly and at intervals reduced the strength of the solution, and finally I went through all the performances entirely without carbolic acid. In the same way with the details which came into use during the performance of the operation. Thus, I used to sponge out the cavity of the abdomen with a solution of one in twenty, but now I use only tepid water, without carbolic acid at all; and in cases where there is troublesome bleeding from separated adhesions I pack the cavity with sponges—as many as twenty at a time—without any carbolic acid in them; or I wash out the cavity with two or three buckets of warm water poured in from an ewer, utterly regardless of germs in either air or water.

This research occupied nearly two years, and all through that time I was carefully on the watch for either symptoms or results which would arrest me in my experiment, and show me that I was in error, and that I must retrace my steps and re-establish Listerism in my practice. But I found none, and as all the details of my practice, up to the first of November last, have been published, I need not weary you with them now. Suffice it to say, that since the time when I may be said to have abandoned the practice of Listerism, I have performed 107 completed operations for the removal of ovarian tumours; and of these there have been only three deaths, or a mortality of 2.8 per cent., besides a large number of other operations for removal of diseased ovaries and tubes, peritoneal and hepatic hydatids, tumours of the uterus and kidney—these having a mortality quite as satisfactory, and a success which has already attracted a wide attention.

The only survivals of the Listerian method which I retain are the instrument and the ligature baths. I keep all my instruments in baths of plain, cold, tap water; and I scald all my ligatures in boiling water before the operation, to get the gum out, and then keep them in cold water. You may ask why do I keep to

this? and I really can say nothing more than that I like to handle the things wet, and I think it prevents the formation of loose blood clots. There certainly can be no question of germs about it, for the water must contain them in abundance; and I make not the slightest effort to destroy those I believe to be in the air.

The conclusions I make, therefore, from my research are (1) that the germs which produce the putrefactive changes in dead tissue are harmless when admitted to the peritoneal cavity in the operations such as I perform upon it. The fatal cases of ovariectomy which I have seen since I gave up the use of carbolic acid—three in one hundred and seven operations—were due to the same cause, the production of heart clot in cases which had been repeatedly tapped; and I believe that if I were called upon to operate on cases which had been tapped, my mortality after ovariectomy would almost entirely disappear.

2. The further conclusions are that none of the Listerian details, nor the system which they constitute in the aggregate, are at all necessary for the proper and safe performance of operations on the abdominal cavity; and that, on the whole, better, and even more, recoveries are made when no carbolic acid is used at all.

At the International Medical Congress, after the evidence of Dr. Keith and myself upon the matter of the spray, Mr. Lister is reported to have said that possibly in ovariectomy the spray is not necessary. If this is to be accepted as the last utterances of antiseptic philosophy, I can only regard it as another illustration of its marvellous mutability.

Not six months ago ovariectomy was quoted as the chief and greatest illustration of the wonders of Listerism; but it happens to be the only surgical area upon which a strict statistical inquiry can be made; and when that is done, Listerism is found absolutely wanting. If germs are so potent in the case of a lumbar abscess, why do they prove so harmless in my cases of suppurating hæmatocoele? If the serous cavity of the knee-joint is so susceptible to septic influences, how does the peritoneum escape? If you cannot remove a cyst of the back without the spray, how do I manage to do without it for a cyst of the belly? If Listerism is essential in removing a piece of dead bone, how is it I can freely dispense with it in removing a slough from the middle of the liver?

I cannot pretend to answer these questions, they are for Mr. Lister and his disciples. All I can say is, that I do not think they can be answered upon the ground of the antiseptic theory.

My own explanation of my success is in the direction of accumulated experience, and an infinite care over every detail; and I am quite prepared to admit, and I have frequently admitted, that in this direction Mr. Lister's details have done a great deal of good. It yet remains to be proved whether or not an equal success might not be obtained for a series of amputations or excisions if they were conducted, as my research was, by all the Listerian details being carried out with plain tap water.

I do not know, Mr. President, if my remarks fall upon my audience with anything like convincing force; but I am sure you will give me credit for the sincerity of my conclusions, and a desire that they should be dealt with at least as a tentative, perhaps a suggestive, effort.

Nothing in surgery is final; and even if the antiseptic theory and practice be all that is claimed for it, I can only urge that we have not yet got to the end of our tether, and that we have a great deal more to learn.

What you may get out of my paper I cannot say, but I have had at least this, an excuse for having one of my greatest treats—a visit to Dublin.

PUERPERAL FEVER. (a)

By R. H. MEADE, F.R.C.S., J.P.,

Consulting Surgeon to the Bradford Infirmary, and to the Fever Hospital.

In opening a discussion upon puerperal fever I must state in the outset that my object is rather to gain than to impart information. I shall not attempt to give a complete account of the history, symptoms, morbid appearances, or treatment of the complaint, but only try to point out a few of the more prominent features of the disease, with its varieties, &c., calling attention to some of the different opinions and theories, as to its real nature and causes, and thus hope to elicit much valuable information from the members of the Society, both on these points, as well as on the best means to be adopted for its prevention and cure.

The older physicians and writers on midwifery were well aware that there was a dire and fearfully fatal disease of the character of malignant fever, accompanied or produced, as they generally thought, by inflammation of the peritoneum, or uterine organs—sometimes rapidly following the birth of a child, which was much more common in lying-in hospitals than in private practice, and which was evidently and highly contagious; but they entirely failed to trace the source of the infection, or the real nature of the complaint. Dr. Robert Ferguson, one of the earliest professors of midwifery in King's College, was the first who distinctly declared that the essence of the disease was a *poisoned state of the blood*, and the truth of his diagnosis has been amply confirmed and universally recognised since.

Women in the puerperal state are liable to slight *ephemeral forms* of fever; are these of the same nature as the more malignant forms? Some, as for instance, the fever which often attends the first secretion of milk, when it comes with a flush, suddenly and in large quantity, are evidently not, but there are some others which, though never violent or dangerous, are still tedious and troublesome, accompanied with some uterine or abdominal pain and tenderness. In the opinion of some these are like the malignant forms, of the same nature, and also due to poisoned blood; though the dose of poison is much smaller. This is a fair point for discussion. My own opinion is, that they are similar in nature, but different in degree, but if so, are they infectious? I think not.

It being admitted that the essence of the disease is a poison in the blood, the next questions are—

1. What is it?
2. Where does it come from?
3. Are there more poisons than one?
4. How does it find its way into the blood?

Before alluding to the answers which have been given to these questions, I must mention the fact that the blood of the puerperal woman has been shown by Dr. Richardson and others, to be in a peculiar state. Very rich in fibrine, and therefore, peculiarly liable to coagulate and form thromboses, or clots. This fact tends to explain some of the phenomena of puerperal fever, especially those in the pyæmic forms. Now with regard to the queries propounded, I will take the last first, viz., How does the poison find its way into the blood? During the act of parturition more or less abrasion or laceration of the genital organs often takes place, especially in instrumental and first labours, forming a ready and immediate way of entrance for any poison which may be either in the air of the hospital ward, or on the hands or clothes of the physician or nurse. Poison may also enter the uterine sinuses, after the separation of the placenta in those cases where, from debilitating causes, such as flooding, the uterus has imperfectly contracted.

Now with regard to the nature of the poison, and where it comes from. It is pretty generally supposed that there are two distinct sources: one called *autogenetic*, which

(a) Read before the Bradford Medico-Chirurgical Society, March, 1882.

arises independently of infection, from the decomposition of blood, or portions of placenta, &c., in the woman herself. The chemical products of such decomposition, called *sepsia*, being directly absorbed into the blood through the wounds or openings which I have pointed out, producing rapid symptoms of poisoning. Dr. Matthews Duncan thinks that these cases are essentially different from the others (to be presently mentioned). He calls them cases of *sapremia*, in contradistinction to those of true *septicæmia* and *pyæmia*. His theory is that here, the poison is purely a chemical one, and unconnected with parasitic influences. On this account he considers that they are more amenable to treatment. The second source of infection, named *hetero-genetic*, is that in which the poison is derived from without, and we now come to the question of whether there are more poisons than one, and, if so, whether different kinds are capable of producing similar effects or symptoms? No doubt, the most effective cause and the one most to be dreaded, is the poison or contagion derived from another case of a similar kind; this is why puerperal fever is so much dreaded in a lying-in hospital. This might be supposed to be the specific poison, if there be one, but the same effects have been produced by the septic or decomposing fluids which have contaminated the hand of the student or physician, who has been dissecting, or performing a post-mortem examination. Again, the peculiar poison of erysipelas, scarlet fever, and even typhus or typhoid, and diphtheria have been supposed, in many instances, to have given rise to true puerperal *septicæmia*, and not to their own special forms of fever or inflammation. There is little doubt but that this is quite true, at least, as far as erysipelas is concerned. Some pathologists have thought that, owing to the peculiar state of the blood in a puerperal woman, when putrid or malignant fever is set up by the absorption of any kind of septic or morbid virus, a special poison is generated which will very easily produce the same disease in another person. In favour of this view is the fact that attendants and nurses often suffer when waiting upon patients with puerperal fever, but do not do so when attending upon ordinary cases of surgical *pyæmia*.

The last point to debate upon this part of the subject is, whether there is any *real difference* between puerperal *septicæmia* and the ordinary forms of the same disease? I shall leave this open for discussion.

We now come to a very interesting but at the same time very obscure part of our subject—viz., the influence of germs, or bacilli, in the production of *septicæmia*. Dr. M. Duncan thinks that in simple *sapremia* they play no part. He says: "The fœtor of discharges forms no part of *septicæmia* or *pyæmia*; the bacteria or micrococci of these diseases flourish where there is no fœtor." I cannot agree with him, and confess that I can see no real difference between the absorption of self-generated and imparted septic matter. Dr. Burdon Sanderson says: "Both *septicæmia* and *pyæmia* are characterised by the existence of microzymes in the infected fluids, and the intensity of the infection is indicated by the number and character of these bodies, so that in the more intense forms of the disease the exudative liquids and blood are crowded with active bacteria." I can give no opinion on the point whether these fungoid bodies are the *cause* or *essence* of the disease and produce the infection, or whether they are only concomitants. I shall only add on this subject that no one *form of bacillus* seems to be peculiar to any one form of *septic disease*. Extended researches may clear up this and other points connected with this obscure subject.

The symptoms of puerperal fever are *rigors*, *quick pulse*, and *respiration*, *high temperature*; sometimes *delirium*, *vomiting*, and *purging*; *tyimpanitis*, suppression of milk, and lochial discharge; sometimes *no pain*, at others, uterine and abdominal pain and tenderness.

As to *treatment*—first, preventive. In the cases of self-infection (*sapremia*) from putrid discharges it is of great importance that no portions of placenta or membranes are left, nor clots in uterus. Firm contraction of

uterus should be secured by ergot, or other means, particularly after flooding or instrumental delivery. If any fœtor begins the vagina should be thoroughly and frequently syringed with carbolic or other antiseptic lotion. Should any symptoms of mischief arise, most energetic steps must at once be taken. The hand should be introduced (under chloroform if necessary), and pieces of placenta or clots be searched for. If anything is found in the uterus, and it is not firmly contracted, it should be washed out (by the medical man himself) with carbolic lotion (1 in 30 or 40) two or three times a day. Ergot should be given three or four times a day, to cause contraction, &c.; and general treatment by stimulants be adopted.

Cases of true *septicæmia* are to be managed, so to say, rather than treated. With regard to the preventive treatment a very wide question is opened. No doubt can be entertained of the contagiousness of this affection; therefore every precaution must be adopted by the medical man and nurse to prevent all risk of their infecting the patient themselves. Avoid going from a case of erysipelas or scarlatina to a labour without changing clothes and disinfecting hands. Do not perform a post-mortem, if possible, before going to a puerperal case. At the time of attending the labour anoint the fingers and hand well with carbolic ointment. In lying-in hospitals women are now sometimes delivered under spray, and carbolic lotion is freely used to wash the patient and hands of nurses, &c. Midwifery practitioners should be very careful about the state of their hands; infection sometimes appears to hang about them for weeks. If so, the most probable place where it can linger is under the nails. If suspicious of the right, use the left hand.

With respect to the point of going to or attending midwifery *while* or soon *after* attending a genuine case of puerperal fever, a serious question arises, which I will not attempt to solve.

Treatment of TRUE Puerperal Fever.—When the disease has once set in, we cannot hope to cut it short. It will be better to use antiseptic injections to the vagina, whether there be fœtor or not; but it is of no use to inject the uterus by itself. We must treat symptoms as they arise. Tincture of green hellebore has been given, and also tincture of aconite, to bring down the pulse (*in the early stages*); quinine in large doses, or salicine, to lower the temperature. Turpentine has been recommended, both internally, by mouth, and in enemata, and externally for tyimpanitis. Tincture of iron may be tried, as in erysipelas. Iodoform has also been recommended internally by Professor Maggioli, of Rome (the doses are not mentioned by Professor Maggioli). Nourishment and stimulants *in moderation* are all-important, but, unfortunately, the irritable state of the stomach often greatly interferes with the administration of both food and medicines. Though the danger in these cases is very great, still they are not hopeless. The cases of so-called *sapremia*, if treated energetically, will often quickly mend, though the patient may appear *in extremis*. In the other forms, the more chronic they are the greater the hope; and even in cases of *pyæmia* (pus in the blood), when abscesses have formed in joints, the patients have recovered.

Clinical Records.

NOTES ON A CASE OF IDIOPATHIC (?) PERI- AND ENDO-CARDITIS.

By J. S. McDONAGH, M.R.C.S.

I HAVE been led to publish the notes of the following case which occurred in my practice, as being an example of a rare and somewhat unrecognised class of cases. We are led by the text-books to believe that acute affections of the heart are always secondary to some specific state of blood-poisoning (rheumatic, pyæmic, or scarlatinal), but in the following case

there has been no trace of evidence of any precursory symptoms of this sort whatever. The facts are briefly these:—

K. M., set. 6, was brought to me first on November 28th, 1881, on account of listlessness and languor. She had been in the habit lately of lying about the room instead of playing, being generally a very active child. On inquiry I was further told that she had complained for the last few days of a pain over "the pit of the stomach," had lost appetite, and had once or twice vomited in the middle of the night. They were particularly surprised at her being ill, as she was usually so well in the winter, but always "fell away" in the summer. Was thought to have been losing flesh for the last eighteen months. On examination I found the child well nourished, though pale, with a dull, heavy look, skin fairly moist, and tongue furred; complained of slight pain on pressure over epigastrium. Thinking the case one of simple bowel derangement, I ordered some saline tincture and grey powder.

Nov. 29th.—At 9 p.m. I was sent for to see the child, said not to be so well; the symptoms appeared about as on previous day, but temp. 101° 2'; no rash or pain (except slight pain on pressure over epigastrium). Tongue slightly furred.

30th.—Better. Temp. 100°.

Dec. 1st.—Still better. Temp. 99°.

I now saw the case no more till Dec. 6th, when she was brought to me again for some tonic treatment, as she did not seem to get strong. On Dec. 10th I was sent for to see her. Had complained of pain on previous evening over the region of the heart. This led me to make a physical examination, when I found the heart sounds almost inaudible, rendered so by excessively loud rasping, superficial friction sounds, which were to be heard distinctly over the whole of the chest and back, the area of cardiac dullness increased and elevated, pulse 120; deficient expansion of left side of chest; considerable dullness at bases of both lungs, though more marked on left side. Temp. 102° 6'; no cough; no pain anywhere.

11th.—Friction not quite so loud. Pulse 128. Respiration 40. Temp. 102°.

12th.—Temp. 101° 4'. Passes very little urine, which contains a slight trace of albumen; no anasarca, or oedema.

On the 14th the temperature had declined to 99°, and the friction had now quite disappeared, the first sound distinct, but the second sound was replaced by a blowing murmur most distinct about the centre of the sternum, and at the back. Lung symptoms remain as before; no cough.

On the 15th she was seen with me in consultation by Dr. T. B. Peacock, who diagnosed endo-carditis, with probable congestion of the lungs, and fluid in the left pleura.

On the 16th the temperature became sub-normal—97° 6', and remained so on the 17th. The murmur is gradually diminishing in intensity and area over which it is distinctly heard; child more lively.

18th.—Temp. normal.

Jan. 4th.—The murmur in front is now only to be heard in front of chest over the mitral area, but is conducted round into the axilla; the dullness at the bases of both lungs not so marked, but at the back the normal heart sounds are not to be heard, a single sound being heard at each systole similar in character to the puff of an engine. The child seemed in the best of health and spirits.

11th.—An examination yielded results similar to the previous one.

23rd.—Heart's impulse not nearly so violent, no undue impulse to be seen or felt; on auscultation the pitch of the murmur and area over which distinctly heard remains unchanged, but there is a sharp clicking sound at moment of closure of the valves. At the back the murmur is most distinctly heard over the right back. Lungs now quite resonant. All symptoms of anæmia quite passed away.

Treatment consisted in at first perfect rest with simple ante-febrile medicine with digitalis; when the fever had passed away, quinine and iron with digitalis, and cod-liver oil. Locally, mustard leaves applied every night.

Remarks.—I have entered fully into the precursory symptoms of the illness in order to show that there were none of the ordinary specific or rheumatic symptoms present: the question then arises whether this is really a case of idiopathic disease or not? At a meeting of the Medical Society of the College of Physicians in Ireland, on December 7th, 1881, Dr. W. Smith related three cases of idiopathic pericarditis, but in two at least of these cases there was distinct evidence of rheumatism. Of course, as was pointed out on the occasion referred to, there may be a rheumatic affection of the pericardium without any other symptoms of rheuma-

tism at all; but would such a supposition in the case narrated cover also the severe endo-carditis which co-existed? If not, then, could the case have been one of ulcerative endo-carditis, with secondary inflammation of the pericardium. We know that such cases are by no means rare, but are, unfortunately, seldom recognised. There is generally, however, a history of rigors at the commencement of the disease, which was entirely absent in this case, and, furthermore, often a distinct source of infection is recognisable. Dr. Wilks speaks of this disease as "arterial pyæmia," and deals with the subject exhaustively in a lecture published in the *British Medical Journal* of Jan. 14th, 1882; he shows there how these cases are really states of blood-poisoning, and suggests a local source of self-infection when there are no general symptoms. He quotes four cases in support of these theories, but in three of these there was a distinct history of rheumatism. I think that the case quoted requires further explanation than seems at present ascertainable.

Transactions of Societies.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

TUESDAY, MARCH 7th, 1882.

The President, Dr. CRAIG, in the Chair.

MR. R. H. MEADE, F.R.C.S., read a paper on

PUERPERAL FEVER.

which will be found on page 246.

Dr. W. WHEALEY said, until those gentlemen who are more accurately and deeply versed in the subject of puerperal fever have had time to collect their thoughts, I will venture to make a few remarks on one of the ablest and most practical papers to which it has been my privilege to listen. Mr. Meade has briefly given us both the ancient and modern views of the etiology, pathology, and treatment of this disease, and his numerous admirable remarks relative to the prevention and treatment of this malady are so suggestive that one might easily occupy an hour in their discussion. Out of nearly three thousand cases of midwifery, attended during the past twenty years, I cannot call to mind a single case of so-called puerperal fever in my practice. I have seen a few cases of puerperal fever in Bradford during that period, and these were treated on the principles laid down by Mr. Meade, viz., by the exhibition of quinine, beef-tea, and stimulants, and the uterus was washed out with the carbolic lotion. I am inclined to the belief that modified cases of puerperal fever do occur, but think that scarlatina and puerperal fever are distinct diseases.

Mr. P. MIALI raised the question whether puerperal fever is one disease, or only a name given to a variety of conditions that are really distinct. Mr. Meade had treated mainly of the septicæmic forms of the disease. The experiments of Braidwood which tended to show that the lochial discharge is poisonous when applied to an abraded surface were mentioned.

Dr. TREBITS said that puerperal fever was more frequent in the towns than in the country where there was less crowding. He was of opinion that the frequent use of the forceps by causing abrasions was one cause of the affection. At any rate, notwithstanding greater knowledge, mortality in childbed was no less now than years ago when forceps were rarely used. With regard to microzymes being present in the blood that was of no importance, as such organisms were far too general and had no definite specific characters. He had seen two very bad cases in which there were the following symptoms:—pulse 140° or upwards, temperature 106°, tympanitis, profuse sweating, and delirium. The treatment in each case was 10 grains of quinine twice a day, and a tablespoonful of brandy every hour; they both recovered. The first case was evidently autogenetic, the second heterogenetic. He asked Mr. Meade what the latest date was after delivery when puerperal fever might come on. He had seen a case of pneumonia coming on fourteen days after labour, having all the symptoms of puerperal fever. He was doubtful if the carbolic spray in lying-in hospitals had anything to do with preventing the disease, this arose more likely from greater cleanliness and sanitary precautions.

Dr. RABAGLIATI said he had not had a large experience of puerperal fever, though the experience he had had, had been extremely painful, and had made a strong impression on his

mind. He disagreed with Dr. Tibbits, and thought on the contrary, that tediousness of labour was a predisposing cause, rather than too great rapidity. One important point overlooked in the paper, and by previous speakers, was the predisposing influence of mental depression. In the most shocking case he had ever seen, depression seemed to him to have so lowered the vital powers, that even if the woman had not been about to be confined, he thought she would have sickened from something else, say phlegmonous erysipelas. In this opinion Dr. Howie, of Liverpool, concurred. As to syringing, he highly approved of that, but in a very bad case he had done with his own hand all that was possible to be done in this way, four times a day; and yet the patient died after of phlebitis of the leg, diphtheritic throat, swelling of the joints, abscess behind the ear, and pneumonia; in short, of blood-poisoning. He threw out as a suggestion in such cases, free drainage as in surgery, by the passing of a drainage-tube into the uterus, and said that should it ever again be his misfortune to see another case, he should employ this in addition to the other recognised means of treatment.

Dr. GOYDER remarked that the value of the discussion depended upon the speakers importing into it their own experience of cases. The causes of this affection, in absorbed septic matter, or direct contagion from infected subjects, through the uterine sinuses, or abraded surfaces of the uterus and vagina, or through infected air into the lungs; and the resultant pathological states of the uterus, peritoneum, and other organs were better understood than formerly. He had seen cases both of the inflammatory and adynamic variety, the former coming on forty-eight hours after labour and dying within the week, and characterised by violent metritis, and hysterical symptoms, profuse perspiration, and ultimate collapse, in which the treatment of calomel and opium and salines was of little avail. In the latter variety the patient sunk in a week, from diarrhoea, despite stimulants and support. He was now accustomed, whenever the pulse and temperature rose after labour, and the lochia were offensive, to wash out the uterus twice a day with water and Condy's fluid, and to administer ammonia and carbolic acid (1 in 100); and by these means he believed he had prevented what would otherwise have become puerperal septicæmia. He was not of opinion that scarlatina was a common cause of this affection; he had seen a woman take scarlatina two days after labour without bad results, and in another case where two children were lying dead in a one-roomed house from scarlatina, with a parturient woman, no injurious effects were produced upon her. The poison seemed more allied to erysipelas, and was more purely septic than zymotic in character. Antiseptic precautions in the medical man, and extreme cleanliness of the patient would go far to prevent the disease.

Dr. BURNIE said: In the exhaustive paper we had heard from Mr. Meade, it had been pointed out how the puerperal woman was peculiarly liable to the invasion of disease. In this aptitude she was placed in a dangerous position towards the contagion of erysipelas, scarlatina, and other maladies; she was the easy subject of pyæmia, and the facile victim of septicæmia. Peritonitis sometimes was the consequence of labour though not so frequently, in his opinion, as was generally supposed, metritis and phlebitis. All such morbid conditions, and others, were brought within the designation of puerperal fever; but he believed there was no specific fever deserving such denomination, and then a great majority of cases called, were referable to poisoning of the blood through the walls of the vagina or uterus, and that the grand remedy was to be found in antiseptic methods of treatment, such as he had the honour of pointing out in this room some five years ago, in his address to the Yorkshire Branch of the British Medical Association.

Mr. APPELEYARD said that a more careful clinical study of the progress of natural labour, especially in regard to elevation of temperature, was necessary, and would aid greatly in throwing light on cases of puerperal disease. He had made it a rule to do this in his cases, and found it very common to have a rise of temperature as labour progressed, but as a rule, a normal temperature was reached by the end of 24 or 36 hours. Especially where premature labour was induced, he had noticed, steady rise of temperature for two or two and a-half degrees. Three cases in his practice had interested him much. *Case 1.*—Had a natural labour, and the same evening (previous to the labour) the husband had a rigor and became ill, with symptoms of phlebitis of superficial

veins of the front of the thigh, later on, endocarditis, and died in about 19 days from blood-poisoning. Cause unknown. Wife and husband were in separated rooms, door to door, and under my care. The wife had no febrile reaction of any kind, except during establishment of the flow of milk. *Case 2.*—Placenta prævia. Tenth morning after confinement at ninth month, just after taking breakfast, became very ill, vomited, and continued to do so for some hours, temperature ran up almost directly, or at least within one hour, the temperature in the mouth was 105°. Pain in lower part of abdomen. The retention of clot was suspected, 3j. dose of liq. ergotæ was given, and in the course of a quarter of an hour, a laminated ball of pale decolourised fibrine, the size of a small orange, was expelled from the uterus. The fever abated, although it continued for some days and the case did well. *Case 3.*—One of premature labour induced between seventh and eighth months, for pelvic deformity, was discharged quite well at the end of second or beginning of third week. About thirtieth day after labour she began to have very severe diarrhoea, but did not have any medical attendance for four days, when she was compelled to go to bed, complaining of rheumatic pains all over, but chiefly in flexures of joints, and along flexure surfaces of limbs, and presently phlebitis of superficial veins, first of the calves of both legs, and in the course of five or six days, of fronts of upper and forearms; also, there was pleuritic friction on the left side, and an endocardial murmur; pulse for some days above 140; respiration rapid, and profuse perspiration. The patient, however, recovered very slowly and is now alive. The child also survives.

Dr. MURRAY (Burley), said he had a very limited experience of the important disease brought so ably under their notice by Mr. Meade, having only had one case in his own practice in eighteen years. He had always thought it arose from self infection, and occurred in women whose vital powers were feeble from whatever cause, for in such there was little power to resist the fatal effects of septic matter when it had been absorbed. In many respects puerperal fever was not unlike typhoid in the manner of its onset, the nature of the initiatory symptoms, and the efforts of nature to throw off the poison by a profuse diarrhoea. The only point he could not explain was its contagious nature, for we must admit that it was occasionally contagious. That puerperal fever killed more rapidly than typhoid could be explained by the greater amount of septic matter getting into the blood, and the diminished power of resistance.

Mr. MEADE said, in reply to Mr. Miall, that he did not regard this affection as several different diseases, but as simple septicæmia. There could be no doubt of its infectious nature, which had been proved again and again by medical men and midwives. As to Dr. Tibbit's questions as to the length of time after labour when a woman could take it—possibly any time within a month if exposed to contagion; as to the question of carbolic spray in hospitals preventing the affection, there was proof that it did. He thought there was some truth in the too frequent use of the forceps, young men, as a rule were in too great a hurry to get their cases over, and injuries from forceps predisposed to the absorption of putrid matter if it was present. A very slow and tedious labour might lead to it in a different way, the soft parts got injured, the uterus did not contract so well, and her depressed state laid the patient open to attack. Putrid lochia would not produce the fever in every case, you must have the peculiar constitutional conditions besides. There were cases of puerperal peritonitis and phlebitis also, which were not puerperal fever or septicæmia.

SURGICAL SOCIETY OF IRELAND.

A MEETING of the Surgical Society of Ireland was held on Friday evening, Feb. 24th, in the Albert Hall, Royal College of Surgeons,

Dr. BARTON, Vice-President of the College, in the chair.

Mr. TUFNELL, Hon. Sec., read the minutes of the previous meeting, which were confirmed.

RUPTURE OF JEJUNUM FROM EXTERNAL VIOLENCE.

Mr. W. HEPBURN showed the jejunum of a man, æt. 47, who was admitted to the Meath Hospital in February suffering from the effects of a fall on the stomach. He said he had fallen from the edge off a table, that he had been struck he knew not by what, and had been doubled up. Symptoms

of peritonitis developed next morning. At the autopsy the mesentery and great omentum were greatly congested, and adhesive lymph was present in great quantity; there were signs of pus in some places, the cavity of the peritoneum contained ochreous fecal matter in considerable quantity, which was found to pour through an opening in the jejunum, about three feet from its commencement. The rupture was found to be nearly circular with everted edges. The intestine was slightly constricted at the point of rupture, and was greatly congested. The other viscera were intact.

NECROSIS OF RIGHT TEMPORAL BONE.

Mr. ARTHUR BENSON showed a large sequestrum of the right temporal bone taken from a child, $\text{et. } 3\frac{1}{2}$ years. The child first came under his care in St. Mark's Ophthalmic Hospital about a year ago suffering from double otorrhoea and necrosis of both mastoid processes, with sinuses opening externally. Eight months before the child had had scarlatina, after which the running was noticed from both ears, but nothing was done to stop it until pus began to come from behind the ear as well as through the meatus. The mass of diseased bone could be felt with probes, but was too firmly fixed to attempt its removal with the forceps. She was sent out, and last January she again came to the hospital; the bone was considerably more movable, but could not be removed. She was, therefore, again sent to the country, and on last Saturday the mother brought the piece of bone exhibited. The specimen consisted of a part of the squamous, mastoid, and petrous portions of the right temporal bone, measuring $1\frac{1}{2}$ inches by 1 inch, by $\frac{1}{2}$ of an inch. The posterior surface of the petrous portion was smooth (though worm-eaten in appearance), and seemed to have given attachment to the dura mater.

Mr. LAWSON TAIT (of Birmingham) exhibited an ovary which he had extracted by an operation on the previous Wednesday, and which was illustrative of the new advances in abdominal surgery. At the Pathological Society in London a few months ago he had shown a number of specimens of diseases which were far more common than any one had the slightest idea of until surgeons began to open the abdominal cavity in suffering women more frequently than they had been in the habit of doing. The patient from whom the ovary on view was extracted was unable to walk more than a few hundred yards, and unable to bear marital intercourse under any circumstances. This condition arose from an attack of pelvic peritonitis at the time of her first confinement. After suffering for five years she accepted to have the abdominal cavity explored. He found the right ovary, now exhibited, in a disorganised condition. The right tube contained about half a drachm or a drachm of pus, revealing an abscess of the cavity; but the interesting thing was the left tube still untouched, which he believed contained pus. He then laid it open with a knife, revealing the ordinary purulent fluid.

Mr. LAWSON TAIT (of Birmingham) read a paper on

A RESEARCH INTO THE VALUE OF THE DETAILS OF LISTER'S METHOD IN ABDOMINAL SURGERY, which will be found on page 243.

The CHAIRMAN said the Society had listened with great interest to Mr. Lawson Tait's valuable paper. The great extent of his experience and the wonderfully successful results he had obtained would lend weight to his conclusions; but it was his wish no doubt to hear what members had to say on one side or the other of the many-sided question of Listerism. As Mr. Tait had argued from his own experience to general conclusions on the subject, it was open to members having other experience to state their views *pro* and *con.*, so as to elicit full discussion.

Mr. ORMSBY said he had listened with pleasure to Mr. Lawson Tait's paper, and, as a member of the Society, he thought he could echo the feelings of every one present when he stated that the Society ought to be very much obliged to the distinguished operating surgeon who had come so far to give them the benefit of his great experience in abdominal surgery. As the time was so short for discussion, he would not enter at length into the merits or demerits of complete Listerism in operative surgery. He believed, however, in certain of the details as carried out by surgeons thoroughly confident in complete Listerism, and in his own practice he adopted what he would term a modified antiseptic line of action. On a previous occasion, when

the subject was before the Society, he stated his views concerning complete Listerism, but was in the minority, and, for all he knew, he might be still in the minority when he said he did not think the entire details of Listerism necessary in the treatment of wounds. He thoroughly believed in modified antiseptics which embraced cleanliness, removal of blood-clot, relief of tension, drainage, exclusion of air, good nursing, isolation, and increased practical experience of the surgeon. When ovariectomy was successfully performed under the spray and with the other details of Listerism, too much credit was given to the carbolic spray as an agent in reducing mortality; and he believed the successful results were attributable to modified antiseptic treatment. Having heard Mr. Tait's paper disclosing the success attending his abdominal sections without the spray, he was convinced that in these operations, at any rate, the carbolic spray need not be used.

Dr. ATTHILL remarked that he had come to listen, not to give his own opinion, which he shrunk from stating, when he heard a gentleman telling the Society he had opened the abdomen one hundred times. He had, however, opened the abdomen probably as often as any other Irish surgeon, and, therefore, he would express his views. When a man of such great experience as Keith, of Edinburgh, had completely changed his opinion, he did not think any one present should hesitate or think it wrong to change his opinion, if shown to be erroneous. He had letters from Keith not more than a year ago in which he stated that, under the spray, operation had become so absolutely safe that the surgeon could keep the abdominal cavity open for an hour or so. Now, however, Keith told him he was under a mistake, and that his previous experience was altogether altered. Having had a run of seventy or eighty cases consecutively of successful ovariectomy in which the spray was used, he had two or three fatal cases which he attributed to carbolic acid poisoning. Mr. Keith was incapable of saying a word that he did not believe to be absolutely true, and his experience was so extensive, and the care he took in his operations so great, that his errors were very few. Anything he had said, therefore, should be received with respect. Turning now to his own experience of the spray, it was not what he would have wished or expected. His first two ovariectomies were both successful. At the time these took place the spray was not used at all, nor he believed even heard of. The first one was exceedingly simple—the cyst turned out as a nut would from its shell, and the patient got rapidly well. Dense adhesions had to be separated, but the cyst was removed, and the patient got well without a single bad symptom. These were two as successful cases as any man could have. Since he became attached to the Rotundo Hospital he had performed thirty operations or more of ovariectomy, in nearly every one of which, but not all, he had used the spray. As far as his opinion went, he did not see any very great difference in the results, whether the spray was used or not; but for some time past, and before Listerism began to go a little out of fashion, for the last six months, he had come to the conclusion that there were certain definite objections to the use of the spray in abdominal section. The chief objection was the extreme coldness produced in the abdominal cavity. His own hands were cold; the intestines were cold; and the chill was enhanced, not by the carbolic acid, but the spray playing on the abdomen. Hence, he removed the spray to a distance to prevent it from falling on the abdomen at all. In one case he observed symptoms which led him to believe that there was also carbolic acid poisoning; but that case was an exceedingly bad one, almost hopeless, and that the patient sank rapidly and died; was not to be wondered at. On the whole, as far as he was concerned, he hailed with satisfaction the idea that the carbolic acid spray was not necessary. It was most irksome to an operator and produced extreme coldness on the abdomen, and, as far as his experience went, it was not at least absolutely essential. As to whether carbolic acid should be used in cleansing the sponges he was not prepared to give an opinion, but it appeared to him to be beneficial to use a weak solution.

Dr. FITZGIBBON considered they should all speak with a certain amount of diffidence to the opinion of Mr. Lawson Tait, as there was not a surgeon in Dublin who had anything like his experience of abdominal section and ovariectomy. But he was old enough to remember the time when, in Dublin, ovariectomy was looked upon as almost certain death to the patient, and there was no surgeon in a

general hospital who would face the operation. Now, however, it was his good fortune to see the operation performed successfully over and over again in Dublin within the last few years under the carbolic acid spray. He had had four cases himself, all of which he operated on under the carbolic acid spray, and all did well. He believed his first was the first case in which ovariectomy was done in Dublin under the spray. In another of the cases there was a suppurating cyst which burst into the abdominal cavity, and yet the patient recovered. On the other hand, he could not recall a single instance of a recovery in a general hospital in Dublin from ovariectomy performed, within the last five years at all events, without the assistance of carbolic acid spray. In this he might be wrong; but certainly he had never been present himself at any operation—and he had witnessed a great many—in which recovery followed that it had not been carried out under the spray. He thought the profession in Dublin would admit that the introduction of Listerism in this particular operation had been followed by an amount of care in the minutiae and success in the results never attained before, and he should be sorry to see the carbolic acid spray cast aside in Dublin, even upon the authority of so successful an operator as the distinguished visitor.

Mr. WHEELER said he would not enter into the subject of whether Listerism really carried out what it proposed, whether it destroyed germs, or whether germs were not found in the cases where the spray and gauze had been used just the same as in those cases treated without Listerism. But coming to the subject of abdominal surgery, he had not had great experience in it, nor had his results been as successful as Dr. FitzGibbons's, though he thought he had used the carbolic spray before the cases alluded to by him. He took every precaution to have Listerism carried out most accurately as Lister described it; he had had two sprays going, and the operation passed off favourably and well. But without any reason, or any cause that could be ascertained, the patient suddenly got quick pulse, suppression of urine, and death followed at three o'clock the next morning after the operation. For a long time he could not think what was the cause of this. He attributed it to accumulated shock, such as was described by the older surgeons. He thought, however, she died from the spray. Without entering into his own experience in abdominal surgery, they had the experience of Keith and Spencer Wells, of Mr. Baldwin, and Dr. Bantock. Indeed, Dr. Bantock had stated that since he commenced to lessen the carbolic acid spray, so as to make it incompatible with Listerism, he obtained better surgical results—less surgical fever, his temperature did not run so high, and he had more even recoveries. At the last meeting but one of the Society he emphasised this point that when he reduced the strength of the spray to be incompatible with Listerism, the temperatures were not so high as when the spray was used in accordance with Listerism. Again, in the *British Medical Journal* for Dec. '80, or Jan. '81, Spencer Wells states his opinion that experience has a good deal to do with success, and that in peritoneal operations he had greater successes without, than with, the antiseptic method. Add to that Keith's expression that his patients were so near dying he was forced to give up the spray. But, moreover, Lister himself had stated that, under careful hands, he thought the spray might be given up in ovariectomy, and he had no doubt the peritoneum could take care of its own exudates. These were his words with regard to abdominal surgery. Without taking up more time, he thought it was clear that Listerism did not carry out what it was intended to do and as claimed for it by, he might say, without meaning to be offensive, the partisans of his practice. Cheyne showed that Listerism failed to destroy the bacteria or germs floating in the air, since they were found in the suppuration of the wounds in spite of the spray, which was supposed to wash the air of them. True, some said they were not to have any suppuration in Listerism, but Lister himself did not state that. What they really had to thank Lister for was, that he had impressed upon them more cleanliness than they practised before. Drainage was the essential part of Listerism, but it was not Lister who first brought it forward. They all knew that if they had sufficient drainage they would not have bacteria—at least, bacteria could not live in wounds of a certain density. The bacteria would be harmless, as stated by Naegeli. His own experience was as he had observed—that his temperatures ran higher under Listerism than under the ordi-

nary treatment, and he was fortunate enough to publish a paper stating his views on the point before Bantock's, which appeared about the same time, coinciding with what he had put forward.

Mr. CORLEY admired the moderation with which Mr. Lawson Tait had stated his case, supported, as it was, by extraordinary statistics and experience. He had not, however, heard any discussion of his arguments. Mr. Lawson Tait commenced by an admission of the germ theory. That was a most important point—the admission that the germs, when introduced into the human organisation, were capable of producing disastrous consequences.

Mr. LAWSON TAIT.—Only in dead tissue.

Mr. CORLEY.—Into the living tissues when dead tissue is in contact?

Mr. LAWSON TAIT.—No. The tissue must be absolutely dead.

Mr. CORLEY.—And not in contact with the living?

Mr. LAWSON TAIT.—I have nothing to do with that. That is another question.

Mr. CORLEY said it was an important matter. Mr. Lawson Tait introduced gallons of water into the peritoneal cavity in which he found cysts of abscesses and quantities of pus. He was not certain whether or not Mr. Lawson Tait would hold that those quantities of pus were still living material. But his practice was not in accordance with his admission of the germ theory of putrefaction and its results. That seemed to be a weak point in Mr. Lawson Tait's admirable paper. It seemed as if Mr. Lawson Tait was adopting the system of modified antiseptics which had been described. In defence of Lister, he did not think Lister claimed as much for the Listerian system, spray, &c., as some of his opponents attributed to him. It would seem, from the observations of some of the speakers, that the use of the spray was intended to supersede experience, dexterity, and, he thought, even brains. But Lister never meant that, and any one who heard him speak on the subject would be satisfied that his modesty was equal to the amount of industry he had exhibited and the advance made by his method, whether the correct one or not.

Dr. MACAN said his experience was also limited. All the details of Listerism might not be necessary, and that increased experience would enable them to eliminate some of the details there could be no doubt. At the same time when they looked to the germ results and pyæmia before Listerism was introduced, and the increased success in ovariectomy by about 400 per cent. more than before, it should be acknowledged that Listerism had a wonderful effect in regenerating surgery. What were the exact essentials of Listerism required to be seen, and the most important point, therefore, was to find out how much of Listerism could be eliminated without throwing the whole of it away.

Mr. THOMSON said anyone who had taken an interest in the discussions that had taken place concerning the subject of antiseptic surgery must have been struck by two things—first, the pertinacity with which the attacks have been made upon the method, and secondly, the fact that the opponents of the system were not always logical. In the first place, they admitted certain things—they admitted that there were germs in the air. (Mr. Darby, No.) Some of them did, at all events. They admitted that those germs had a certain influence upon dead animal matter. But when pressed into a corner, though having granted the premises of the argument, they at once refused to accept the consequence. They refused to adopt what were, to his mind, the strict logical conclusions which followed. Mr. Lawson Tait was no exception to that class of opponents, through the whole alphabet of them, from Mr. Savory down to Mr. Wheeler. Mr. Lawson Tait did believe in germs, and did believe in their effect, but, strange to say, he did not believe in septicæmia. "The terms septicæmia and septic peritonitis," he said, "are simple nonsense."

Mr. LAWSON TAIT.—I did not say that. Read the context.

Mr. THOMSON.—Mr. Tait wishes me to read the context. In one of his pamphlets he used these words, "The terms septicæmia and septic peritonitis, for which Mr. Spencer Wells is mainly responsible, and which have appeared in the mortality column as the explanation of the deaths after ovariectomy, are simple nonsense." As to the subject of septicæmia, he supposed Mr. Lawson Tait had read a series of papers from the pen of Marion Sims in the *British Medical Journal*, and his experience in abdominal surgery would not be questioned. Sims was very emphatic on this, that patients

have been dying from the beginning of time, as to whom the cause of death has been attributed to peritonitis, though, in reality, they died of septicæmia. Mr. Lawson Tait had, in one of his pamphlets, also said that he had succeeded in bursting the very largest and the most attractive bubble ever blown in connection with surgery, and that was Listerism. It was only natural, therefore, that when Mr. Lawson Tait had a bubble of his own to blow, there should be some examination of the conditions under which that process was effected. The first series of fifty ovariectomies that that gentleman published were done non-antiseptically, and the result was a mortality of 38 per cent. He found in a pamphlet by Mr. Knowsley Thornton that that was a mortality greater than any other British surgeon had ever achieved. In the second series of fifty ovariectomies, which Mr. Lawson Tait performed antiseptically—i.e., with the antiseptic precautions of Lister—the result was, that instead of having a mortality of 38 per cent., it fell to 6 per cent. He did not know the result of the third fifty; but the Society had heard the extraordinary success Mr. Lawson Tait had achieved by his process of elimination. He had laid particular stress upon the actual method which he described, attributing his success, first, to the treatment of the pedicle; secondly, to his increased personal experience; and thirdly, to a general improvement in the conditions under which the operations were performed. The question of experience came in at once. There was no doubt that experience had a great deal to do with all operations, whether abdominal or not. But Mr. Lawson Tait would not feel flattered if he were described as an ordinary surgeon—he was a very distinguished surgeon, of very great perception and observation, and of audacious enterprise, at all events. What would Mr. Lawson Tait do with the men who had merely to perform one or two operations in the course of their lives? or half a dozen, or even twenty?—how were those men to arrive at the experience which he had attained through several hundreds of operations? Were they to experiment on the abdomens of women, and pour in buckets of water, and do all the other things which Mr. Lawson Tait did. Mr. Lawson Tait had succeeded in obtaining his results by that process; but one of the main causes of his success he had set down as experience. Looking to the experience of surgeons who had but a small field of operation, they obtained by the antiseptic method as great a success. Mr. Tait considered that it would be dangerous as attended with too much mortality to perform the operation in general hospitals. But the experience of some surgeons present, who belonged to general hospitals was, that with the antiseptic precautions of Lister, the operation might be successfully performed. In the Richmond Hospital, for instance, where all kinds of surgical cases were taken in, since they began to use the Listerian method, they had succeeded in obtaining excellent results. Of eight done under the Listerian treatment, seven recovered. The patient that died had been frequently tapped, and was brought up from the country practically in a dying condition. Every one of the other seven—and one of them was the removal of the uterus—recovered; and every one of Dr. Fitzgibbon's four recovered. In the *Edinburgh Medical Journal* lately, Dr. Angus McDonald gave fifteen cases antiseptically done with two failures, which were explained. In addition to these, he had a letter from Mr. Lister stating that Hector Cameron, of Glasgow informed him that eight ovariectomies "have been performed during this winter session in the densely-crowded operating theatre of the Western Infirmary (in connection with the University). Two of these cases were Dr. Cameron's first ovariectomies, and four of the others were by a comparatively young surgeon. Some had been very bad cases, but all the eight had recovered; a contrast in results with those of former practice in Glasgow, which Dr. Cameron could only ascribe to the use of antiseptic means, including the spray." Then, Mr. Knowsley Thornton, of the Samaritan Hospital, London, mentioned that of the last fifty cases, some of which were done as Mr. Lister informed him by a young surgeon, only two cases died, and these were both cases of malignant disease. All these were done under the spray. If they were to follow Mr. Tait's argument, the want of experience in some of these operators ought to be felt in those cases, yet they had been uniformly successful. A great deal of capital had been made of Mr. Keith's recantation. But in the paper originally published on the subject, Keith laid down that the spray was neither

troublesome nor inconvenient, and tabulating the results that he had obtained from Listerism he stated—first, that it had lessened the mortality; secondly, its increased safety would encourage medical men to recommend earlier operation which few now did; thirdly, with antiseptic ovariectomy, the drainage tube would not be nearly so often required; fourthly, convalescence was rendered easier; and, fifthly, antiseptics were a great comfort and relief to the operator. After 80 operations done by the antiseptic method, without a single death, Keith had the misfortune to get some cases of what he thought were carbolic acid poisoning. Terrified by the result, he argued from a small experience to a universal conclusion, abandoned the spray altogether, and condemned Listerism. Now, in St. Bartholomew's Hospital, it was a notorious fact that before Listerism was adopted in the wards in which the gynecological cases were treated, there had been a very serious mortality in ovariectomy, but when the operator (Mr. Smith, he believed it was) adopted that method—and Mr. Lister informed him that he had Dr. Matthews Duncan's authority for stating it—"they had had excellent results, a change which they could only attribute to the introduction of antiseptic measures." There was a general hospital where both plans were tried; and Mr. Tait would acknowledge Mr. Smith's ability, and that he did his best for his cases. They could judge of the results. But the question to be decided in connection with antiseptics was not so much the number of cases that recovered out of the number treated, as how many they were able to save out of the number that had a tendency to death. There was always a large margin of persons who recovered naturally, whether treated antiseptically or the reverse. But the question was what were they to do with the margin of people who had a tendency to die? That was the point on which antiseptic surgery had done its best. It might be that in the salubrious and calm air of Birmingham there were better conditions for good results from the opening of the abdomen; but in the disturbed atmosphere of Dublin he did not think they had reached a condition in which they would be justified, whether as general surgeons or gynecologists, in setting aside all those precautions, and adopting at once the method which Mr. Lawson Tait had brought forward. There was no doubt the results were very brilliant; but then it was another question whether they would accept the lesson which he wished to teach, and which he (Mr. Thomson) thought a dangerous one, and whether that lesson would lead at once to the success which he had attained.

Dr. HENRY KENNEDY mentioned that Spencer Wells had gone on rapidly improving long before carbolic acid was introduced, and he was lessening the mortality in his operations. So there must be something besides carbolic acid to produce the result.

Mr. KENDAL FRANKS remarked that at the International Congress Mr. Lister mentioned that the great successes attained by those who had given up the antiseptic treatment were due to the great experience of the operator and his careful attention to details. Hence the surgeons who had not the experience of Keith, must avail themselves of methods which would supplement to a certain degree, if not replace, that great experience. Carbolic acid as an antiseptic was a crutch, and he was not ashamed to lean upon it. Up to the beginning of last year his experience of antiseptic surgery was not very prominent—he used it to the best of his knowledge with results which he did not think he could obtain any other way. A friend of his from Vienna, who had seen Billroth using it, told him that Billroth thought little of the carbolic acid spray; but what struck him as remarkable was the trouble Billroth took to wash thoroughly the part with carbolic lotion. From the beginning of 1861 to the present his experience of antiseptic surgery had been completely revolutionised. He had observed the greatest care in washing the part thoroughly with carbolic solution before beginning to operate, and he had seen union by first intention in a great many cases where there were large wounds.

Mr. CROLY said he had only a limited experience of abdominal surgery. He had good results in ovariectomy before the introduction of antiseptics as well as after; but he did not wish to confine his remarks to that branch of surgery. The point to which he wished specially to draw attention was in connection with erysipelas and blood-poisoning in the same wards, and under the same conditions, before antiseptic surgery was adopted, and since. When a

student at the hospital of which he was now surgeon, having been successively resident pupil and resident surgeon, he had had an opportunity of observing all the cases admitted. Erysipelas and blood-poisoning were the greatest dread of the surgeon in all cases of operation. Now, however, he could not call to mind the day when he saw either erysipelas or blood-poisoning follow an operation. This was a remarkable fact that the temperature following his operations did not rise. He was no more wedded to Listerism than to any other ism; he was prepared to give up the spray, and all the precautions now so successful in his hands, and to adopt Mr. Lawson Tait's method, if he thought he would have the same result; but he could not let the statement pass uncontradicted that there was greater cleanliness in surgery in 1882 than in 1852. He did not know when he saw blood-poisoning; and such was his confidence in antiseptic surgery, that, though a boy in the ward had erysipelas of the face, he went on with antiseptic operations there. Mr. Lawson Tait's experience which he had detailed did not extend to amputations, excisions, &c., and had he adopted his plan in general practice the question was would he be so great an advocate of it still?

Mr. O'GRADY rose in the cause of truth to say that he had personal experience of the hospital alluded to, and Mr. Tufnell would bear him out when he asserted that erysipelas and blood-poisoning were not rampant. Into Mercer's Hospital, with which he was connected, erysipelas was frequently imported, and it was a very rare thing—not twice a year—for a case of erysipelas to occur in the wards. He could not recollect two cases in six years. He would not place a case of fresh operation purposely next an erysipelas case, but the hospital being small, they had no choice, and he would not feel a bit uneasy. He had not seen erysipelas spread, and he believed the danger of it was very much overrated. They did not practise the Listerian system much in his hospital, and in one or two cases in which it was practised the result was pretty much the same.

Mr. LAWSON TAIT replied. He was gratified at the reception of his remarks, because he came there with the expectation of being, like Mr. Ormsby, in a minority of one. He had not the faintest notion that his views would have been accorded he would not say support, but partial agreement. There were two or three points that had been touched upon by nearly all the speakers, so he would deal with them in a lump. It was perfectly clear from the frank way in which experience of failure as well as of success had been stated they had a far different way of dealing with cases on this side of the channel from the other, where it was too much the custom to say nothing about failures. Mr. Lister had to go to Glasgow to get an illustration of eight ovariectomies done successfully with the spray. But thousands of cases in general hospitals could be published which had died; and he could cap every successful case of Lister's ovariectomies with ten unsuccessful ones. He could not, in the interests of professional decorum, say anything about those cases, as the operators had not published them; if he did, it would be said that he wanted by so doing to bring grist to his own mill. It was sometimes, however, tempting to reply to a man in quoting successful cases; but he had never been drawn into a breach of professional decorum. They had a curious way of working at Bartholomew's, thinking, seemingly, that ovariectomy was a butchery that ought to be done by anybody, and it was performed by the junior surgeon. Mr. Smith had a fair success, and Mr. Willet had a remarkable success. Two of his colleagues, however, did not attribute it to any antiseptic proceedings in a haphazard way, but to Mr. Willet's special power of operating, and the fact that he has had a larger number of cases than any other surgeon in Bartholomew's. He was asked what he should say to a man who had only the chance of doing three or four cases? He should repeat *Punch's* advice to those about to marry, "Don't." Here again he might be accused of bringing grist to his own mill. Dr. Atthill was credited with a large experience in abdominal surgery. Speaking for himself were he a surgeon of a general hospital and asked to perform the operation he would not do it—the game was not worth the candle. A man in England attached to a general hospital in a country town getting a case of ovarian tumour said to himself: "If I do this case there is no credit, of course the patient will get well." If I do it and she does not, there is an awful row; it ought to have gone to Spencer Wells, Keith, or some one else." He could quote large hospitals where hundreds of amputations were done, but where they refused to do ovariectomies.

The other point was a question of his own experience, and that had been dealt with perfectly fairly by Mr. Thomson and he was only surprised that Mr. Thomson did not make rather a harder use of the facts than he did. His first fifty cases had 38 per cent. of mortality, and nobody regretted that more than he did himself. He knew the cause of it: they were nearly all the clamp. In the second fifty they were nearly all intra-peritoneal. The hospital was an old house, altogether unsuited for the purpose, and killed a good many of the patients, and it was his own fault in others. He left the sponge in one abdomen. It was not his fault either, but the assistant's, who tore the sponge in two. But the great mortality in the thirty-eight was certainly the clamp. Dr. Henry Kennedy was not quite right about Spencer Wells, who never ran much, if at all, under 20 per cent. of mortality until he gave up using the clamp, and began using the intra-peritoneal method of Listerism. He did 137 or 157 cases of intra-peritoneal ligature. The line of conduct he pursued was open to very grave objection. Baker Browne began long before Wells, and he had forty cases with four deaths. After that Spencer Wells went on for twelve years using the clamp. Possibly, if Spencer Wells had never touched the clamp, ovariectomy would be the better for his services. Dr. Lombe Atthill had alluded to the cold produced by the spray. He found that such a serious matter that he had a contrivance by which the temperature of the spray never went below 92°, or very little less than that of the body, so that in his experiments that point was not a source of failure. It would occupy too long to go into the question of septicæmia and septic peritonitis. In the details he had given, the cause of death ought to be death from clamp all the way through. If the ligature had been used instead of the clamp the patients would have lived. Hence, what he meant by saying septicæmia or septic peritonitis was nonsense, was that to say that was the cause of death was the nonsense. The use of the clamp, that was pointed out years and years before by Baker Brown to be a wrong thing to use, was what he called nonsense. Mr. Croly had alluded to erysipelas. Here was another difficulty about the Listerian system. Lister was attached to King's College Hospital. He (Mr. Tait) wrote a book on hospital mortality, and of every hospital in the kingdom that published results, King's College Hospital, one of the largest medical schools, was the hospital about which no return could be obtained. He had been with the governors and had threatened them with letters in the *Times*, and done everything that moral persuasion could do to obtain some statistics, but he could not get them. He was told that, for eight weeks at the end of 1880, King's College Hospital—though you could not open the doors without getting a smell of carbolic acid enough to knock you down—was closed because of erysipelas. That might be true or not, but it was the gossip of London. He had been unable, however, to get anything like statistical details. Unless statistical details could be given of general surgery like the accuracy with which it was given in abdominal surgery, he was not prepared to accept mere statements, even when coming from Lister. During last autumn every bandy-legged child in the backyards of Birmingham had had its tibia divided by a chisel and mallet, but it was now given up. He no longer heard of children having their bones divided.

Mr. CROLY.—They are all cured.

Mr. LAWSON TAIT said they were not. They had been dying of pyæmia in spite of Listerism. In Glasgow, where this line was persistently carried out, one surgeon told him he had done as many as 300; but one of his favourite pupils was now giving the whole thing up. He heard of a surgeon who operated by the Listerian method on two children for stone in the bladder. In the first case he opened the peritoneum by mistake. Turning to the pupils, he said it did not matter, it had been done under the spray; but the boy died of septic peritonitis. In that way, and in the same hands, the incident was repeated, although the gentleman concerned had published contributions in which success was the only remark. The event in question had never seen the light; but that sort of thing was not fair. They ought not to hear altogether of the successes, and hear nothing of the failures.

The Society then adjourned.

FLEET SURGEON WILLIAM ANDERSON, principal Medical Officer at the Royal Marine Depot at Walmer, died at his official residence on the 15th inst., from acute rheumatism.

REGISTERED FOR TRANSMISSION ABROAD.

THE

MEDICAL PRESS AND CIRCULAR

Is published every Wednesday morning. Price 5d. Post free, 5jd.

POST FREE TO ANNUAL SUBSCRIBERS £1 2 6

IF PAID IN ADVANCE 1 1

* Post-office Orders and Cheques to be drawn in favour of—

A. A. TINDALL, 20 King William Street, Strand, London, W.C.

A. R. JACOB, 3 Molesworth Street, Dublin.

Agents for Scotland:—

MACLACHLAN and STEWART, South Bridge, Edinburgh.

A. and W. STENHOUSE, Hillhead, Glasgow.

SUBSCRIPTIONS FOR FRANCE are received by Messrs. BAILLIÈRE, Rue Hautefeuille, Paris—post free in advance, £1 2s. 6d. per annum.

SUBSCRIPTIONS FOR THE UNITED STATES are received in New York, by Messrs. WILKINS and ROGERS; Philadelphia, by Dr. BRINTON, post free in advance, 5j dollars (£1 2s. 6d. per annum; or direct from the Offices in this country for the same amount, if remitted by International Post-office Order

ADVERTISEMENT SCALE.—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d.; Quarter Page, £1 5s. 0d.; One-eighth Page, 12s. 6d.

Small Announcements of Practices, Assistances, Vacancies, Books, &c., of seven lines or under, 4s. per insertion; 6d. per line beyond. Considerable reductions are made from the foregoing Scale when orders are given for a series of insertions. Letters in this department should be addressed to the Publishers.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 22, 1882.

THE LAMSON CASE.

THAT any other verdict than that which declared the prisoner guilty of a foul and premeditated murder could have been the final result of the Lamson trial, no trained, unprejudiced reader of the wonderful scientific evidence could possibly doubt. All that could be done on behalf of the accused man by a brilliant and eloquent advocate was done to ameliorate the damning character of evidence which carried conviction to the minds of the jury; but nothing could weaken the irresistible strength of testimony contributed by Nature's unanswerable response to experimental inquiries. The case, indeed, must rank in the future as the most remarkable and instructive of any that have engaged the attention of medical jurists. It has served to demonstrate with startling clearness how definite, how decisive, how subtle the science of physiological chemistry has become in the hands of its most competent living teachers; and with the sorrow we are compelled to experience at the spectacle presented by a member of the noblest of all professions arraigned on a charge the most hideous conceivable, is mingled also a feeling of triumph that the very profession thus publicly outraged has contributed the witnesses whose evidence secured the murderer's conviction. To Dr. Stevenson especially must be accorded the most unstinted praise. Not only did he conceive and carry out a series of masterly experiments to prove the nature of the poison administered to Lamson's unhappy victim, but even in the witness-box, subjected to searching cross-examination by one of the most skilful defenders at the bar, he maintained the dignity and infallibility of the science he so worthily represented. The

position he occupied was, moreover, one of unusual difficulty. The whole array of facts presented by him was of a kind to receive no support from antecedent research; while each and all depended on the strictest reading of scientific results.

An occasion of this sort is perhaps the most favourable that could offer for trying the real worth of the unassisted testimony of the laboratory; it has most indubitably shown the reliability of such evidence to a majority of thinkers; but, notwithstanding, there are signs already of willingness on the part of a few to gainsay the results achieved. By-and-by, when the heat of the moment gives place to calm reason, we doubt not that regret for momentary mistaken enthusiasm will be felt by such objectors, and especially do we venture to think that those who have availed themselves of the daily press to give utterance to adverse opinions in this connection will be sorry for the haste with which they rushed into print in conflict with such unanswerable arguments as were advanced by Dr. Stevenson at the late trial. We cannot forbear reference here to a letter contributed to the *Echo* newspaper of Saturday last by Mr. J. Alfred Wanklyn, a chemist of deserved reputation in some respects, but hardly such as to justify him in attacking the evidence of chemists who enjoy at least an equal eminence with himself. In the letter referred to, Mr. Wanklyn has the courage to assert "The extreme uncertainty of the taste-test in this and analogous instances is a matter of notoriety amongst chemists, and nothing is plainer to me than that the conditions under which alone any kind of reliance ought to be placed in such tests have not been complied with." This is certainly a grave accusation to bring against the witness on whom the onus of proving the presence of aconitine in the dead body chiefly rested, and taken with a preceding sentence in the same letter, it places the writer in a somewhat invidious position. After describing the evidence at the trial as unsatisfactory, Mr. Wanklyn proceeds to "state his opinion that the presence of aconitine has not been made out to the satisfaction of persons who have special knowledge on these subjects." We may perhaps be permitted, without undue inquisitiveness, to inquire who are the persons here spoken of? If Mr. Wanklyn is cognizant of deaths produced by poisoning with aconitine he enjoys a unique experience; if he is not, no "special knowledge" on the subject can be claimed by him, since information directly gained is the only "special" knowledge here admissible. During the trial there were, fortunately, no distressing conflicts of "expert" testimony witnessed, and we can now perceive with greater clearness the justice of the decision which refused leave for any such volunteered service. To the mind of every competent chemist the presence of the alkaloid aconitine was proved in the clearest possible fashion, and we trust that Dr. Stevenson will not be prevailed upon now to enter on a paper warfare in defence of his conclusions. In any case lay papers cannot be regarded as a proper medium for correspondence on this matter, nor do we think anyone with the interests of science and justice really at heart will take such means of obtruding his theories of the case.

The trial is calculated to have an important influence on the question of experimenting on animals for purposes of research; and it may, not improbably, awaken the dying

energies of anti-vivisectionists in one last effort to stir afresh popular indignation against the advance of truth. Their inaction of late, however, would seem to indicate despair of doing further injury by their mischievous exertions; and if this be so, we shall escape the usual flood of nonsensical literature which was formerly the invariable sequel to every publication of a physiological experiment. Whatever tactics, however, may be pursued by this party of obstruction, the utility of such experiments, apart from the discoveries they may lead to, can no longer be denied; but for them the only unanswerable proof forthcoming of a murderer's guilt would have been wanting; whereas, now, through the sacrifice of a few insignificant mice, unerring testimony to the commission of an iniquitous crime has been obtained.

In another connection, also, the Lamson trial will not be without its good results. Dating from it, we may expect to find the history of cadaveric alkaloids will be more fully investigated; and although in this particular case none of the conditions essential to their existence were fulfilled, it will not be without some advantage by stimulating inquiry into a very important and at the same time all but unknown class of decomposition products. In the whole masterly structure of the defence there was no more ingenious point raised than this of cadaveric alkaloids. Against the possibility of any reliance on it, however, were three fatal objections, which effectually and for all disposed of it. These were that the body of the murdered boy was not decomposed when the poison it contained produced fatal effects on animals it was injected into; that the vomited matter, preserved in alcohol, and thus free from decomposed substances, gave indisputable proof of aconitine; and that we have no proof that cadaveric alkaloids are capable of producing the physiological effects of normal vegetable alkaloids.

Application has been made to the Home Secretary for a respite of the sentence passed on Lamson, on several grounds, among the reasons given being two chiefly interesting to us—viz., that the jury were not composed of medical experts, and the unreliability of the experiments made with mice. The first of these can need no serious consideration. The evidence was of a kind, more than is usually so in murder cases, to approve itself to the non-scientific mind. The symptoms of poisoning by aconite were carefully explained to the jury, and the evidence was such as to prove conclusively that these very symptoms were observed. Dr. Stevenson's testimony, moreover, was especially such as a child might comprehend; the only difference an expert jury would have made would have been to shorten the time in which the verdict was arrived at, and which even now is made one of the grounds of application for remission of sentence. Of the objection to the experiments made by Dr. Stevenson it is needless to speak further. No competent judge of their value and importance can hesitate a moment as to their weight; we venture to think none does so.

On every ground the Lamson trial will take rank as of high importance in a medico-legal sense; and as to the justice of its result we think no question can be raised.

THE FELLOWSHIP EXAMINATIONS OF THE IRISH COLLEGE OF SURGEONS.

AMONGST the reforms of system to which the Council of the College have devoted themselves within the past year, and to which we have referred from time to time, not the least important to the College is that with reference to the future Fellowship examinations. The scheme for an improved system has been under consideration by the Council and its sub-committee for some month past, and it has received last week the final approval by the Council, which makes it allowable for us to lay it before our readers. Heretofore it has been the rule of the College to impose the full measure of the examination set forth in the Bye-laws upon junior candidates for the Fellowship, but to grant certain exemptions to those who had been over ten years in practice. These concessions to seniority and proved experience went in the direction of making the examination more a practical, clinical, and operative test than a test of book-study and anatomical work, and this principle has been followed up in the new regulations to which we refer. These concessions to senior candidates were, however, not properly defined, but were left very much to the discretion of the examiners, and thus it happened that—according to the varying interpretation of the rules by different examiners—the examination came to be a very erratic test, and while some candidates were severely criticised by the Court, others were passed on a nominal examination. In order to define the procedure for the information of the candidate and the instruction of the examiner, the Council has graded the candidates into five classes:—

- a. The student who has no previous qualification.
- b. The L.R.C.S.I. who is of less than ten years' standing.
- c. The Licentiate of other Colleges of same standing.
- d. The L.R.C.S.I. of more than 10 years' experience; and
- e. The Licentiate of other Colleges of same period of work.

These grades will be in future examined as follows:—
